2
3 **Abstract**
4
5
6

7 *Background:* Notch signaling controls a number of cellular processes, including
8
9
10 cell fate decisions, proliferation, differentiation, and survival/apoptosis, in multiple
11
12
13 tissues. In the epidermis, Notch1 functions as a molecular switch that controls the
14
15
16 transition of cells from an undifferentiated state into a differentiated state.
17
18

19
20
21 *Objective:* To clarify the functions of Notch in the regenerated epidermis during
22
23
24 wound healing.
25
26

27
28 *Methods:* Wounds on mouse skin were immunostained. To investigate the
29
30
31 functions of Notch, Notch was inhibited in primary keratinocytes by treatment with
32
33
34 a γ -secretase inhibitor and by small interfering RNA-mediated knockdown, and
35
36
37 was activated by a recombinant adenovirus approach.
38
39
40
41

42 *Results:* Notch1 and Notch2 were down-regulated in the regenerated epidermis
43
44
45 during wound healing. To clarify the significance of this down-regulation, we
46
47
48 examined its effect on expression of the interleukin (IL)-1 family of
49
50
51 proinflammatory cytokines because wounds are exposed to pathogens from the
52
53
54 outside world. Among the IL-1 family, IL-36 α expression was induced by Notch
55
56
57
58
59
60
61
62
63
64
65

1
2
3 inhibition. This was consistent with the decreased IL-36 α expression in
4
5
6
7 Notch-overexpressing keratinocytes. Notch down-regulation in the regenerated
8
9
10 epidermis may reinforce defense against stress from the outside world by
11
12
13 inducing IL-36 α expression. Next, we examined the effects of Notch
14
15
16 down-regulation on keratinocyte growth and differentiation. Notch
17
18
19 down-regulation did not alter keratinocyte proliferation. On the other hand,
20
21
22
23 Notch1 down-regulation suppressed induction of spinous layer-specific keratins
24
25
26
27 (keratin1 and keratin10) in keratinocytes, which was consistent with the
28
29
30 decreased expression of these keratins in the regenerated epidermis. The
31
32
33
34
35 reduced levels of these keratins would increase cellular flexibility.
36
37

38 *Conclusion:* Notch down-regulation in the epidermis appears to contribute to
39
40
41
42 tissue regeneration during wound healing.

1
2
3 **1. Introduction**
4
5

6
7 Notch (Notch1–4 in mice and humans) is a transmembrane receptor that
8
9
10 regulates cell fate decisions during development and contributes to the
11
12 maintenance of cell proliferation, differentiation, and survival/apoptosis. Notch
13
14 signaling is initiated by ligand-receptor interactions between neighboring cells. In
15
16
17 response to ligand engagement, Notch undergoes proteolysis by γ -secretase.
18
19
20
21 This releases the Notch intracellular domain, resulting in translocation of the
22
23
24 intracellular domain into the nucleus, where it binds to the DNA-binding protein
25
26
27
28 CSL. While CSL functions as a transcriptional repressor by binding to the
29
30
31 promoter regions of particular genes, it is converted into a transcriptional
32
33
34
35 activator by association with Notch, resulting in activation of downstream target
36
37
38
39 genes, such as Hes and Hey [1-3].
40
41
42
43
44

45
46 Notch activation is generally thought to maintain stem cell potential and
47
48
49 inhibit differentiation. However, in some cell types, such as keratinocytes,
50
51
52 increased Notch activity causes cell-cycle exit and commitment to differentiation,
53
54
55
56 whereas down-modulation or loss of Notch1 function promotes carcinogenesis
57
58
59
60
61
62
63
64
65

1
2
3 [4,5]. Keratinocytes form a multilayered stratified epithelium, the epidermis, which
4
5
6
7 comprises basal, spinous, granular, and cornified layers. Each of these layers is
8
9
10 characterized by specific expression of a repertoire of keratins and other proteins
11
12
13 [6]. Notch1–3 are expressed in the epidermis, and their activation is considered
14
15
16 to regulate skin homeostasis [7,8]. Postnatal knockout of Notch1 leads to a
17
18
19 hyperproliferative epidermis due to interference with the commitment of basal
20
21
22 cells to differentiate into spinous cells [4,5]. This suggests that Notch1 functions
23
24
25 as a molecular switch that controls the transition of basal cells into spinous cells.
26
27
28
29
30

31 The epidermis is a barrier-forming tissue that protects the internal milieu from
32
33
34 the outside environment; therefore, keratinocytes are the first to respond to injury.
35
36
37

38 After injury, keratinocytes are activated and secrete various cytokines, including
39
40
41 interleukin (IL)-1, which alert surrounding cells to barrier damage and attract
42
43
44 inflammatory cells to the wound site to remove contaminating bacteria.
45
46
47

48 Simultaneously, re-epithelization is a crucial step, which involves the migration
49
50
51 and proliferation of keratinocytes at the periphery of the wound to cover the
52
53
54 denuded dermal surface. If this process is dysregulated, patients will require
55
56
57
58
59
60
61
62
63
64
65

1
2
3 long-term care of their wounds and are at increased risk of infection and fluid loss.
4
5

6
7 In this instance, migrating keratinocytes undergo various modifications beyond
8
9
10 cytokine secretion. In healthy epidermis, keratinocytes exhibit a columnar
11
12
13 phenotype and are tightly connected with neighboring keratinocytes. However, as
14
15
16
17 the cells start to migrate across the wound bed, keratinocytes become flatter and
18
19
20
21 more elongated, which requires dramatic reorganization of their cytoskeleton [9].
22
23

24 Basal keratinocytes usually express keratin 5 (K5) and K14, whereas spinous,
25
26
27
28 differentiating keratinocytes express K1 and K10. However, in the regenerated
29
30
31 epidermis, K1 and K10 expression is attenuated and replaced by K6, K16, and
32
33
34
35 K17 expression. While abundant expression of K1 and K10 in the context of
36
37
38
39 normal epidermal differentiation promotes increased mechanical resilience, the
40
41
42
43 abundance of these keratins disturbs the pliability of keratinocytes, leading to
44
45
46
47 retardation of their migration. The transition from K1/K10 expression to
48
49
50
51 K6/K16/K17 expression likely reflects a compromise between conflicting needs
52
53
54
55
56 i.e., retaining sufficient cell pliability for migration, while acquiring sufficient
57
58
59
60
61
62
63
64
65 resilience to survive in the wound environment [9].

1
2
3 Cutaneous wound healing is a highly coordinated physiological process that
4 rapidly and efficiently restores skin integrity. We found that Notch expression was
5
6
7 decreased in the regenerated epidermis. Notch may play a role in epidermal
8
9
10 regeneration. To better understand the role of Notch in wound healing, we
11
12
13 analyzed the effects of Notch down-regulation on keratinocytes.
14

23

24 **2. Materials and Methods**

25 *2.1. Cell Culture and Reagents*

26
27
28 Primary keratinocytes were prepared from the epidermis of newborn ICR
29
30
31 (Institute for Cancer Research) mice, as described previously [10]. In brief, the
32
33
34 epidermis was separated from the dermis with 0.25% trypsin (Gibco BRL, Tokyo,
35
36
37
38 Japan), plated in dishes precoated with collagen type I (Nitta Gelatin, Osaka,
39
40
41
42 Japan), and cultured in minimum essential medium supplemented with 4%
43
44
45 Chelex-treated fetal calf serum, epidermal growth factor (10 ng/ml; Gibco BRL),
46
47
48
49 and 0.05 mM CaCl₂. Under these conditions, keratinocytes are maintained in an
50
51
52
53
54
55
56
57
58
59
60
61
62
63
64
65 immature state, and differentiation was induced by the addition of CaCl₂ to a final

1
2
3 concentration of 2 mM. For migration assays using the scratch method,
4
5
6 keratinocytes were grown to confluency in 60-mm culture dishes and a scratch
7
8
9 was made through the monolayer with a 200- μ l pipette tip. Cells were further
10
11
12 incubated, and the scratch areas were filled by migrating cells. Images of more
13
14
15 than six fields were captured, and migration into the scratch area was analyzed
16
17
18 using ImageJ software. Recombinant adenoviruses expressing either LacZ,
19
20
21 Notch1 intracytoplasmic domain (a constitutively active form of Notch1), or
22
23
24 Notch2 intracytoplasmic domain (a constitutively active form of Notch2) were
25
26
27 generated, as described previously, and were used at a multiplicity of infection
28
29
30 (MOI) of 50 [10]. The adenovirus expressing LacZ was used as a control. The
31
32
33 following antibodies were purchased and used as recommended by their
34
35
36 suppliers: goat anti-Notch1 and goat anti-Notch2 polyclonal antibodies (Santa
37
38
39 Cruz Biotechnology, Santa Cruz, CA); rabbit polyclonal antibodies against K1,
40
41
42 K5, K6, and K10 (Covance, Emeryville, CA); mouse anti-tubulin- α monoclonal
43
44
45 antibody (Sigma, Tokyo, Japan); mouse anti-bromodeoxyuridine (BrdU)
46
47
48 monoclonal antibody (BD Biosciences, Tokyo, Japan); rabbit anti-Ki67 polyclonal
49

1
2
3 antibody (Novocastra, Wetzlar, Germany); rabbit anti-phospho-epidermal growth
4
5
6
7 factor receptor (EGFR) monoclonal antibody and rabbit anti-cleaved Notch1
8
9
10 polyclonal antibody (Cell Signaling Technology, Tokyo, Japan); goat anti-IL-36 α
11
12
13 polyclonal antibody (R&D Systems, Tokyo, Japan); and fluorescein
14
15
16
17 isothiocyanate (FITC)-coupled and horseradish peroxidase-conjugated goat
18
19
20
21 anti-mouse and goat anti-rabbit IgG antibodies (Amersham, Tokyo, Japan).
22
23
24 N-[N-(3,5-difluorophenacetyl)-L-alanyl]-S-phenylglycine t-butyl ester (DAPT), a
25
26
27
28 selective inhibitor of γ -secretase, was purchased from Cayman (Ann Arbor, MI).
29
30
31
32
33
34

35 *2.2. Wound Formation and Immunostaining*

36
37
38 Female mice (8–10 weeks old) of a C57BL/6 background were anesthetized
39
40
41
42 by intraperitoneal injection of 300 μ l of 2.5% avertin. Full-thickness skin wounds
43
44
45
46 were created on the back of each mouse using a 4-mm biopsy punch. To obtain
47
48
49
50 regenerated skin samples from the biopsied areas, mice were euthanized by an
51
52
53 overdose of sodium pentobarbital and the tissues were subsequently removed.
54
55

56 As regenerated skin, recently re-epithelialized areas were obtained before the
57
58
59
60
61
62
63
64
65

1
2
3 skin defect closed. This study was carried out in strict accordance with the
4
5
6
7 recommendations of the Guide for the Care and Use of Laboratory Animals of
8
9
10 the National Institutes of Health. The protocol was approved by the Animal
11
12
13 Research Committee of Shinshu University (permit number: 240030). All efforts
14
15
16 were made to minimize animal suffering. Formalin-fixed samples were sectioned
17
18
19 at a thickness of 4 μ m. Frozen skin sections (6 μ m thick) were fixed with 2%
20
21
22 paraformaldehyde or cold acetone. Non-specific binding was blocked using 5%
23
24
25 serum, and the skin sections were incubated with primary antibodies and
26
27
28 subsequently with isotype-specific secondary antibodies. After immunostaining,
29
30
31 nuclei were stained with 4',6-diamidino-2-phenylindole (DAPI; Invitrogen, Tokyo,
32
33
34 Japan). Stained preparations were observed with a LSM 5 exciter (Zeiss, Jena,
35
36
37 Germany).
38
39
40
41
42
43
44

45
46 In addition, DAPT was topically administered to the skin on the backs of mice.
47
48
49 Mice were shaved under anesthesia 2 days prior to treatment with DAPT. On
50
51
52 day 0, Scotchguard (3M) tape was firmly applied to the hairless area and
53
54
55 removed in a sudden motion three times to eliminate the horny layer. Thereafter,
56
57
58
59
60
61
62
63
64
65

1
2
3 DAPT (100 µl of a 100 µM solution prepared in DMSO) was topically applied

4
5
6
7 three times every other day. As a control, DMSO was topically applied.

8
9
10
11
12
13
14 *2.3. Immunoblotting*

15
16
17 Proteins were extracted from cultured keratinocytes and subjected to
18
19 immunoblotting, as described previously [10]. In brief, electroblotted membranes
20
21 were blocked with TBST (50 mM Tris [pH 7.5] and 0.5% Tween 20) containing
22
23 5% non-fat dried milk. The membranes were then incubated with primary
24
25 antibodies, rinsed with TBST, and incubated with peroxidase-conjugated
26
27 secondary antibodies. After additional rinses, the blots were exposed to
28
29 LumiGLO reagent (Cell Signaling Technology). Equal loading was achieved by
30
31 normalization of the protein concentration using a bicinchoninic acid protein
32
33 assay (Pierce, Rockford, IL).
34
35
36
37
38
39
40
41
42
43
44
45
46
47
48
49
50
51
52

53 *2.4. BrdU Incorporation*

54
55
56 Cells labeled with BrdU for the last 5 hours of cultivation were permeabilized
57
58
59
60
61
62
63
64
65

1
2
3 in 0.1% NP-40 and denatured in 50 mM NaOH. BrdU incorporation was detected
4
5
6
7 using an anti-BrdU antibody. The total number of nuclei was determined by
8
9
10 fluorescence microscopic observation of nuclei stained with DAPI. At least six
11
12
13
14 fields were assayed per sample (> 100 cells/field).
15
16
17
18
19
20

21 *2.5. Quantitative Reverse Transcription-PCR (qRT-PCR)*

22
23

24 Total RNA was extracted from cells using TRIzol reagent (Invitrogen), as
25
26
27 recommended by the manufacturer. cDNA was synthesized using Moloney
28
29
30 murine leukemia virus reverse transcriptase (Promega, Madison, WI) and 3 µg
31
32
33 of total RNA as the template. qRT-PCR analyses were performed using a
34
35
36
37
38 StepOne™ RT-PCR System (Applied Biosystem, Tokyo, Japan), a LightCycler
39
40
41
42 System, and a Universal Probe Library Set (Roche Applied Science,
43
44
45 Indianapolis, IN). Primers and probes were purchased for Notch1, Notch2, Hes1,
46
47
48 K1, K10, and hypoxanthine phosphoribosyl transferase (HPRT) from Applied
49
50
51
52
53 Biosystems. Furthermore, specific primers were designed to sequence one

47 3.1. *Decreased Expression of Notch1 and Notch2 in the Regenerated Epidermis* 48 49 *during Wound Healing* 50 51 52 53

54
55 To clarify the roles of Notch in wound healing, we examined Notch
56
57
58
59
60
61
62
63
64
65

1
2
3 expression in the regenerated epidermis. In intact mouse skin, Notch1 was
4
5
6 expressed in the basal and spinous layers, while labeling was absent in the
7
8
9 upper layers. Notch2 was observed throughout all epithelial cell layers, with
10
11
12 weak expression in the basal layer. The intensities of Notch1 and Notch2
13
14
15 labeling were decreased in the regenerated epidermis during wound healing (Fig.
16
17
18 1A). Next, we examined the expression of Hes1, a downstream molecule of the
19
20
21 Notch signaling pathway. Similar to Notch expression, the intensity of Hes1
22
23
24 staining was decreased in the regenerated epidermis (Fig. 1B), showing that
25
26
27 Notch function was reduced during epidermal regeneration. Furthermore, we
28
29
30 examined activation of EGFR because this receptor is reportedly a key negative
31
32
33 regulator of Notch1 expression [11]. The intensity of phospho-EGFR staining
34
35
36 was increased in the regenerated epidermis inversely to the intensities of Notch1
37
38
39 and Notch2 staining (Fig. 1C). In addition, expression of Notch1 and Notch2 was
40
41
42 restored after closure of the skin defect (Fig. 1D); thus, Notch expression was
43
44
45 reduced in the regenerated epidermis.

3.2. Notch Down-Regulation Induces IL-36 α Expression in Keratinocytes

During wound healing, regenerated tissues are exposed to the outside world and are therefore vulnerable to pathogen attack. Keratinocytes should alert surrounding cells of this risk to prevent pathogen invasion. We examined whether Notch regulated the production of IL-1 family cytokines, which are induced in response to tissue damage and promote inflammation [12,13]. First, we used a γ -secretase inhibitor, DAPT, to inhibit the Notch signaling pathway by blocking the proteolytic cleavage of Notch. As expected, Hes1 expression was reduced by DAPT treatment (Fig. 2A). Among IL-1 family cytokines (IL-1 α , IL-1 β , IL-18, IL-33, IL-36 α , IL-36 β , and IL-36 γ), DAPT treatment only increased the mRNA expression of IL-36 α (Fig. 2B); expression of the other members was not induced by DAPT treatment. The increase in IL-36 α expression was confirmed at the protein level (Fig. 2C). To verify that IL-36 α expression is increased by Notch down-regulation, we knocked down Notch using sequence-specific siRNA (Fig. 2D). IL-36 α expression was increased by Notch1 silencing, as well as Notch2 silencing (Fig. 2E, 2F). Notch knockdown had the same effects as

1
2
3 treatment with a γ -secretase inhibitor. In contrast to Notch down-regulation, we
4
5
6
7 used an adenovirus to overexpress the intracytoplasmic domain of Notch1 or
8
9
10 Notch2. Overexpression of the intracytoplasmic domain of Notch1 or Notch2
11
12
13 decreased expression of IL-36 α , at both the mRNA and protein levels (Fig. 2G,
14
15
16
17 2H); thus Notch negatively regulates IL-36 α expression in keratinocytes.
18
19
20
21
22
23

24 3.3. Notch Down-Regulation Results in Induction of IL-36 α Expression in the 25 26 27 *Epidermis*

28
29
30
31
32 Next, we examined IL-36 α expression in the regenerated epidermis. In
33
34
35 immunohistological analyses, the intact epidermis did not show clear expression
36
37
38 of IL-36 α , whereas IL-36 α was clearly expressed in the regenerated epidermis,
39
40
41 chiefly in the upper and middle layers (Fig. 3A), and this was inversely correlated
42
43
44 with Notch down-regulation. After closure of the skin defect, the induced IL-36 α
45
46
47 expression disappeared in association with restoration of Notch expression (Fig.
48
49
50
51
52
53 3B). To define the contribution of reduced Notch expression to induction of
54
55
56 IL-36 α expression, we examined IL-36 α expression *in vivo* after topical
57
58
59
60
61
62
63
64
65

1
2
3 administration of DAPT, which inhibits the Notch signaling pathway by blocking
4
5
6 the proteolytic cleavage of Notch. DAPT was applied to the skin surface after the
7
8
9 stratum corneum had been removed to increase its penetration. While DAPT did
10
11
12 not affect the expression of Notch1 or Notch2, it decreased the level of cleaved
13
14
15 Notch1, the active form of Notch1 (Fig. 3C, Supplemental Fig. 1). Application of
16
17
18 DAPT induced IL-36 α expression (Fig. 3D). Therefore, Notch down-regulation
19
20
21
22
23
24
25
26
27
28
29
30
31
32
33
34
35
36
37
38
39
40
41
42
43
44
45
46
47
48
49
50
51
52
53
54
55
56
57
58
59
60
61
62
63
64
65

administration of DAPT, which inhibits the Notch signaling pathway by blocking
the proteolytic cleavage of Notch. DAPT was applied to the skin surface after the
stratum corneum had been removed to increase its penetration. While DAPT did
not affect the expression of Notch1 or Notch2, it decreased the level of cleaved
Notch1, the active form of Notch1 (Fig. 3C, Supplemental Fig. 1). Application of
DAPT induced IL-36 α expression (Fig. 3D). Therefore, Notch down-regulation
seems to help to alert surrounding cells of barrier damage by inducing
expression of IL-36 α in the regenerated epidermis, which is related to induction
of inflammation around the wound.

3.4. Notch Down-Regulation Does Not Affect Keratinocyte Proliferation in the Regenerated Epidermis

Notch functions in the transition of cells from an undifferentiated proliferative state into a differentiated state in which growth is arrested [4,5]. We examined whether Notch down-regulation alters keratinocyte proliferation in the regenerated epidermis. We overexpressed Notch intracytoplasmic domain (a

1
2
3 constitutively active form) in primary keratinocytes. Notch1 induces the
4
5
6
7 proliferation arrest of keratinocytes [5,14]. Similar to Notch1 intracytoplasmic
8
9
10 domain overexpression, Notch2 intracytoplasmic domain overexpression
11
12
13 suppressed keratinocyte proliferation (Fig. 4A). Considering the growth
14
15
16 suppressive function of Notch together with the endogenous expression of
17
18
19 Notch, keratinocyte proliferation was expected to increase upon DAPT treatment.
20
21
22
23
24 However, unexpectedly, DAPT did not alter keratinocyte proliferation (Fig. 4B), in
25
26
27 contrast to keratinocyte-specific deletion of *Notch1*, which accelerates
28
29
30 keratinocyte proliferation [5]. Notch activity may be weak in undifferentiated cells,
31
32
33
34
35 thereby leading to no alteration in cell proliferation upon partial suppression of
36
37
38 Notch signaling by DAPT treatment. Next, we examined keratinocyte
39
40
41 proliferation in the regenerated epidermis. The epidermis at wound edges is the
42
43
44 source of keratinocytes for wound closure because of the removal of skin
45
46
47 appendages in full-thickness skin wounds. Immunostaining of Ki67, a
48
49
50 proliferation marker, did not show an increased number of positive cells in the
51
52
53 regenerated epidermis (Fig. 4C). This is consistent with a previous report that
54
55
56
57
58
59
60
61
62
63
64
65

1
2
3 keratinocytes proliferate many cell diameters away from the proximal wound
4
5
6
7 edge during regeneration [15,16]. Therefore, Notch1 and Notch2 suppress
8
9
10 keratinocyte proliferation, but it is unlikely that Notch down-regulation contributes
11
12
13
14 to growth regulation in the regenerated epidermis.
15
16
17
18
19
20

21 *3.5. Notch Down-Regulation Alters Keratinocyte Differentiation*

22
23

24 Finally, we asked whether Notch down-regulation alters keratinocyte
25
26
27 differentiation in the regenerated epidermis. DAPT treatment suppressed
28
29
30 expression of spinous layer-specific keratins (K1 and K10) (Fig. 5A, 5B).
31
32
33
34 Similarly, Notch1 knockdown decreased K1 and K10 expression (Fig. 5C).
35
36
37
38 Notch2 knockdown weakly decreased K1 and K10 expression (Fig. 5D),
39
40
41
42 suggesting that Notch1 contributes greatly to the expression of spinous
43
44
45 layer-specific keratins. In contrast to Notch down-regulation, Notch
46
47
48 intracytoplasmic domain overexpression increased K1 and K10 expression (Fig.
49
50
51
52 5E, 5F). Notch1 and Notch2 overexpression had similar effects on K1 and K10
53
54
55
56 expression *in vitro*, although the effects of Notch2 intracytoplasmic domain
57
58
59
60
61
62
63
64
65

1
2
3 overexpression were slightly weaker than those of Notch1 intracytoplasmic
4
5
6 domain overexpression. Furthermore, we examined expression of K1 and K10 in
7
8
9 the regenerated epidermis. In parallel with Notch down-regulation, the intensity
10
11
12 of K1/K10 staining was obviously lower in the regenerated epidermis than in the
13
14
15 intact epidermis (Fig. 5G). To further corroborate the involvement of Notch in
16
17
18 K1/K10 expression, we topically administered DAPT to mouse skin. In contrast
19
20
21 to control DMSO-treated skin, inhibition of Notch signaling decreased K1
22
23
24 expression in the epidermis (Fig. 5H), although K10 expression was not
25
26
27 markedly altered. Notch down-regulation likely leads to alteration of spinous
28
29
30 layer-specific keratin expression in the regenerated epidermis, which may help
31
32
33 to increase cellular pliability necessary for epidermal reconstitution.
34
35
36
37
38
39
40
41

42 In addition, we investigated whether expression of K6, K16, and K17 was
43
44
45 altered by inhibition of Notch signaling because these keratins are induced in
46
47
48 regenerated epidermis [9]. In contrast to K1 and K10, the expression of K6, K16,
49
50
51 and K17 was not altered by DAPT treatment (Fig. 5I), suggesting that the Notch
52
53
54 signaling pathway does not directly regulate K6/K16/K17 expression.
55
56
57
58
59
60
61
62
63
64
65

1
2
3 Furthermore, we examined the effects of IL-36 α on the expression of K6, K16,
4
5
6
7 and K17. However, IL-36 α did not alter the expression of these keratins (Fig. 5J).
8
9
10 Finally, we investigated whether IL-36 α altered keratinocyte migration because
11
12
13 of the need for cellular migration in the regenerated epidermis. IL-36 α treatment
14
15
16
17 did not alter keratinocyte migration in the scratch assay (Fig. 5K), suggesting
18
19
20
21 that IL-36 α induction by Notch down-regulation does not play a role in regulation
22
23
24 of keratinocyte migration in the regenerated epidermis.
25
26
27
28
29
30
31
32
33
34

35 **4. Discussion**

36
37
38 Notch signaling controls a number of cellular processes in multiple tissues.
39
40
41
42 We found that expression of Notch1 and Notch2 was decreased in the
43
44
45 regenerated epidermis of wounds, where the features of keratinocytes are
46
47
48 altered. In our analysis, Notch down-regulation contributed to the induction of
49
50
51
52 IL-36 α expression, which would help to alerting surrounding cells to barrier
53
54
55
56 damage. Furthermore, Notch down-regulation suppressed K1/K10 expression,
57
58
59
60
61
62
63
64
65

1
2
3 which would lead to changes in the viscoelastic properties of keratinocytes
4
5
6
7 during regeneration.
8
9

10 Cutaneous wound healing is a coordinated physiological process. While
11
12 rebuilding an effective epidermal barrier over the wound site, the avoidance of
13
14 infections is a high priority. In response to epidermal injury, keratinocytes release
15
16
17 a variety of factors, such as IL-1 α and other proinflammatory cytokines, around
18
19
20
21 the wound [12,13]. Proinflammatory cytokines serve as a paracrine signal to
22
23
24 fibroblasts, endothelial cells, and lymphocytes [17]. Furthermore,
25
26
27
28 proinflammatory cytokines serve as an autocrine signal to keratinocytes,
29
30
31
32 stimulating them to produce other cytokines and growth factors [18]. Here, we
33
34
35
36
37
38 found that among the IL-1 family members examined, IL-36 α was up-regulated
39
40
41
42 upon Notch down-regulation. IL-36 is expressed in keratinocytes and other
43
44
45
46 epithelial cells and refers to three molecules, namely, IL-36 α , IL-36 β , and IL-36 γ ,
47
48
49
50 which have similar biological activities [19]. IL-36 exerts stimulatory effects on
51
52
53
54
55
56 dendritic cells and T helper 1 cells [20]. Therefore, induction of IL-36 α
57
58
59
60
61
62
63
64
65 expression would be beneficial to prevent infection during wound healing. The

1
2
3 Notch-IL-36 α axis likely acts as an early danger signal to stimulate host
4
5
6
7 responses. There are very few reports concerning the mechanism underlying
8
9
10 induction of IL-36 α , and it is unclear how Notch regulates IL-36 α expression.
11
12
13 Based on the inconsistent expression pattern of IL-36 α with those of Notch1 and
14
15
16 Notch2, we hypothesize that Notch may regulate IL-36 α expression in an indirect
17
18
19 manner.
20
21
22
23

24 The cellular features of regenerated skin resemble those in psoriasis, a
25
26 chronic inflammatory skin disease [21]. This resemblance may be related to the
27
28 Notch signaling pathway because IL-36 plays a role in the pathomechanism of
29
30 psoriasis: IL-36 is overexpressed in psoriatic lesional skin [22,23]. Furthermore,
31
32 mutations of the natural antagonist of IL-36, IL-36Ra, lead to the development of
33
34 pustular psoriasis, a subtype of psoriasis [24,25]. In addition, overexpression of
35
36 IL-36 α can lead to psoriatic-like skin inflammation in mice [26,27]. Intriguingly,
37
38 trauma frequently induces new eruptions on non-lesional skin in patients with
39
40 psoriasis (Koebner phenomenon). Similar to regenerated skin, trauma of the
41
42 epidermis may enhance IL-36 α expression due to Notch down-regulation in
43
44
45
46
47
48
49
50
51
52
53
54
55
56
57
58
59
60
61
62
63
64
65

1
2
3 these patients, leading to the development of new eruptions. Wound healing is
4
5
6 different from psoriasis in that IL-36 α expression is decreased until wound
7
8
9 closure. Restoration of Notch expression after wound closure is important to
10
11
12 prevent continued overproduction of IL-36 α and to terminate the inflammatory
13
14
15 reaction. In addition, impaired Notch signaling results in hidradenitis suppurativa,
16
17
18 a chronic recurrent inflammatory skin disease, which further supports the close
19
20
21 relationship between decreased Notch signaling and skin inflammation [28].
22
23
24
25
26

27
28 The viscoelastic properties of keratinocytes are important for rebuilding an
29
30
31 effective epidermal barrier. The features of keratinocytes, such as their keratin
32
33
34 composition, can be altered. Differentiating keratinocytes express K1 and K10,
35
36
37 while the levels of these keratins are decreased concurrent with the induction of
38
39
40 K6, K16, and K17 expression in regenerated epidermis [9]. Notch
41
42
43 down-regulation results in K1/K10 down-regulation. This affects cellular
44
45
46 resilience and pliability because keratins act as a flexible scaffold that enables
47
48
49 cells to resist physical stress. While K5/K14 expression renders basal
50
51
52 keratinocytes pliable and able to undergo directed cell migration, K1/K10
53
54
55
56
57
58
59
60
61
62
63
64
65

1
2
3 expression in differentiated keratinocytes promotes strong mechanical resilience
4
5
6
7 at the expense of cellular pliability [29]. Cellular plasticity is important for tissue
8
9
10 reconstitution; therefore, decreased K1/K10 expression upon Notch
11
12
13 down-regulation enables keratinocytes to adjust their viscoelastic properties. K6,
14
15
16 K16, and K17 assist regeneration because K6/K16/K17-expressing
17
18
19 keratinocytes are an intermediate between K5/K14-expressing basal cells and
20
21
22 K1/K10-expressing differentiated cells [29]. In addition, K6/K16/K17 expression
23
24
25
26
27
28 seems to be independent of the Notch signaling pathway because expression of
29
30
31 these keratins was not altered by treatment with DAPT or IL-36 α . Damaged
32
33
34
35 keratinocytes release prestored IL-1 α / β , which serves as an autocrine signal to
36
37
38 the surrounding undamaged keratinocytes [18]. IL-1 may lead to induction of K6,
39
40
41
42 K16, and K17 expression [30].
43
44

45 IL-36 α expression was induced not only by Notch1 knockdown but also by
46
47
48 Notch2 knockdown, whereas Notch2 knockdown had a limited effect on K1/K10
49
50
51
52 expression. A recent report revealed that Notch1, but not Notch2, triggers
53
54
55
56 keratinocyte differentiation through Rho-associated coiled-coil-containing protein
57
58
59
60
61
62
63
64
65

1
2
3 kinase 1 activation [31], which suggests that downstream signaling varies
4
5
6 among Notch family members. Notch1-ablated epidermis is susceptible to
7
8
9 chemical-induced carcinogenesis [4]. Although the functions of Notch2 in
10
11
12 keratinocytes remain to be fully elucidated, the removal of Notch2 expression in
13
14
15 Notch1-deficient skin increases susceptibility to tumorigenesis [32,33]. In
16
17
18 addition, loss of CSL or presenilin (the catalytic component of γ -secretase and
19
20
21 the core component in signaling of all Notch receptors) results in more severe
22
23
24 developmental epidermal phenotypes than loss of Notch1 alone [7,34]. Notch2
25
26
27 likely also contributes to epidermal homeostasis, including wound healing.
28
29
30
31
32
33
34

35 In the present study, we elucidated the role of Notch in regenerated
36
37
38 keratinocytes. A reduction in Notch signaling alters IL-36 α and keratin
39
40
41 expression, leading to the regeneration of skin tissue. On the other hand, Notch
42
43
44 signaling regulates many other cells aside from keratinocytes in the wound
45
46
47 healing process. Notch signaling activation is required for vascular endothelial
48
49
50 cell proliferation and migration, and topical application of DAPT leads to delayed
51
52
53 wound closure due to effects on endothelial cells [35]. The role of Notch
54
55
56
57
58
59
60
61
62
63
64
65

1
2
3 signaling varies in a cell type-specific manner [2]. However, our results suggest
4
5
6 that Notch signaling plays an important role in keratinocyte regulation during
7
8
9 wound healing, and that regulation of Notch signaling could provide a novel
10
11 strategy for the treatment of wounds in pathological conditions.

Suppression of Notch activity by DAPT. Primary mouse keratinocytes were treated with DAPT (10 μ M, +) or vehicle control (-) for 48 h. Suppression of Hes1 expression, a Notch downstream target, was verified by real-time RT-PCR, using HPRT for internal normalization. (B) Effect of Notch suppression on IL-1 family cytokines. Primary keratinocytes were treated with DAPT (10 μ M, +) or vehicle control (-) for 48 h, after which the mRNA levels of IL-1 α , IL-1 β , IL-18, IL-33, IL-36 α , IL-36 β , and IL-36 γ were analyzed by real-time RT-PCR. Expression is shown relative to that of HPRT. (C) Effect of Notch suppression on IL-36 α expression. IL-36 α protein levels were quantified by immunoblotting. Keratinocytes were incubated with CaCl₂ (Ca²⁺) to induce differentiation and/or with DAPT. The same blot was stripped and reprobed for tubulin- α as an internal control. (D) Knockdown of Notch by specific siRNAs. Primary keratinocytes were transfected with siRNA against Notch1 (N1i-1 and N1i-2) or Notch2 (N2i-1 and N2i-2) or with the scrambled siRNA control (Ctrl). Notch silencing was confirmed by real-time RT-PCR 48 hours after transfection. Expression is shown relative to that of HPRT. (E, F) Effect of Notch knockdown on IL-36 α expression.

1
2
3 Keratinocytes were transfected with siRNA against Notch1 (N1i-1 and N1i-2) or
4
5
6
7 Notch2 (N2i-1 and N2i-2) or with the scrambled siRNA control (Ctrl). Total RNA
8
9
10 was analyzed by real-time PCR with primers designed to amplify IL-36 α . Results
11
12
13 were normalized against the level of HPRT (E). Keratinocytes were incubated
14
15
16 with or without CaCl₂ (Ca²⁺) and then total cell extracts were analyzed by
17
18
19 immunoblotting with antibodies against IL-36 α and tubulin- α as an equal loading
20
21
22 control (F). (G, H) Suppression of IL-36 α expression by Notch1 and Notch2
23
24
25 overexpression. Keratinocytes were infected with a Notch1 or Notch2
26
27
28 intracytoplasmic domain-expressing adenovirus (N1 and N2, respectively) or
29
30
31 with a LacZ-expressing control adenovirus (Ctrl) at a MOI of 50 for 48 h.
32
33
34
35
36
37
38 Thereafter, IL-36 α was analyzed by real-time RT-PCR (G) or immunoblotting (H)
39
40
41
42 as described in the previous panels. In (H), cells were treated with CaCl₂ for
43
44
45 various amounts of time. Data are presented as the mean \pm standard deviation.

26 immunoblotting with antibodies against K1, K10, Notch1, and Notch2 (F). CaCl₂
27
28 (Ca²⁺) was used to induce keratinocyte differentiation. The same blot was
29
30 stripped and reprobed for K5 as the internal control. (G) K1 and K10 expression
31
32 in regenerated epidermis. Expression of K1 and K10 was decreased in the
33
34 recently re-epithelialized area of the skin wound 3 days after injury. Frozen
35
36 sections of regenerated skin and intact skin were immunostained with an anti-K1
37
38 antibody or an anti-K10 antibody and a FITC-conjugated secondary antibody.

1
2
3 (H) Expression of K1 in DAPT-treated skin. DAPT or the vehicle control (DMSO)
4
5
6
7 was applied to the skin, and then immunostaining was performed for K1 and K10.
8
9
10 Arrows: skin surface, dashed lines: dermal-epidermal junctions. Scale bars: 20
11
12 µm. (I) Effect of Notch suppression on the expression of K6, K16, and K17.
13
14 Primary keratinocytes were treated with DAPT (10 µM, +) or vehicle control (-)
15
16 for 48 h, and then the mRNA levels of K6, K16, and K17 were analyzed by
17
18 real-time RT-PCR. The expression is shown relative to that of HPRT. (J) Effect of
19
20 IL-36α on the expression of K6, K16 and K17. Primary keratinocytes were
21
22 treated with IL-36α or vehicle control for 24 h, and then the mRNA levels of K6,
23
24 K16, and K17 were analyzed by real-time RT-PCR. (K) Effect of IL-36α on
25
26 keratinocyte cell migration in a scratch assay. IL-36α did not alter keratinocyte
27
28 migration. Scale bars: 200 µm. Data are presented as the mean ± standard
29
30 deviation. **P* < 0.05; ***P* < 0.01 (Student's *t*-test). These findings are
31
32 representative of three independent experiments.
