A molecular theory is presented in this paper which gives a method of analysis for the mechanical properties of the filler-reinforced elastomers, based upon the conception of the internal deformation and the statistical theory of the rubber-like elasticity.²⁾ By using a suitable model and a few new concepts a proper analysis for such a heterogeneous system is obtained. From the theory the internal mechanism of filler reinforcement is understood. It is made clear that reinforcement consists of three effects: the volume effect, the surface effect and the cavitation effect. From the theory, formulae for the tension, swelling tension, Young's moduli, local stress distribution, strain birefringence, condition for swelling equilibrium, and so on are derived.

1. INTRODUCTION

It has long been recognized that rubbery substances and plastic materials are reinforced by incorporation of suitable powdery substances (: reinforced fillers) which improve their mechanical properties such as elastic moduli, hardness, stiffness, resiliens, solvent resistance, plastic viscosity, tensile strength, tear resistance, etc.

Although numerous attempts have been made to clarify and systematize the internal mechanism of filler reinforcement, there is at present no distinct picture of the mechanism, much less a satisfactory theoretical treatment of the phenomena.¹⁾

As factors obstructing the development of a theory for filler reinforcement the following four problems might be mentioned:

- (1) Lack of a useful and general method of mechanical analysis for the heterogeneous high elastic materials in which rigid particles are dispersed.

Fig. 1 a: Generally supposed a rough model for heterogeneous materials.

Fig. 1 b: Mullins-Tobins's model.

Fig. 2 Adhesion state on surface of particle.

(2) Difficulty in describing analytically the state of adhesion of filler to the chain molecules of the rubber-like substance (referred simply as "rubbery medium" or "medium", henceforth) owing to the variety and complexity of the adhesion. (3) Scanty information and even less analytic representation of the cavitation caused by elongation which is observed characteristically only in filler-reinforced vulcanized rubber.

(4) Very little quantitative knowledge of the effect of the dispersion state of particles on the properties of heterogeneously filled systems. (The term "particle" means a dispersion unit of filler which is not always an ultimate particle in filler powder but is often an aggregation of the ultimate particles).

In order to solve those difficulties, the following treatments are devised. About the difficulty (1), the internal deformation which is to be distinguished from the apparent deformation in heterogeneous system, is defined by a suitable formula. In regard to the problems (2) and (3), a quantitative representation of the adhesion state which consists of the definition of two idealized adhesion states and the mixing approximation of those is devised. It permits an analysis for the states of adhesion and the cavitation without any assumptions of the molecular mechanism on those phenomena. As to

the problem of the dispersion structure (4), an assumption of uniform dispersion of the particles is adopted in this paper.

2. CONSTRUCTION OF MODEL AND ASSUMPTIONS

Suppose that M spherical rigid particles with a radius d are uniformly dispersed in a vulcanized rubber-like substance whose volume is V_r . The volume ratio X of the filler to the rubbery medium and the volume fraction Y of the filler will be given by $X = M(4\pi/3)d^3/V_r$ and $Y = M(4\pi/3)d^3/V$, respectively, where $V = V_r + M(4\pi/3)d^3$ is the volume of the dispersed system. Since the particles are uniformly dispersed in the medium, the center of each particle is located

at the lattice point of a face-centered cubic lattice. Let us consider, schematically, a spherical domain concentric to each particle with a radius D , such as $D = \{(3/4\pi)(V/M)\}^{1/3}$, and regard it as a representation of the dispersed system in the sense of the one-body approximation. This spherical domain is hereafter referred to as the "D-sphere", and against this given name the particle is sometimes called the "d-sphere".

From the definitions of X , Y , D and the others, next relations are clear

$$\left. \begin{aligned} V &= M(4\pi/3)D^3 = V_r(1+X), \\ Y &= M(4\pi/3)d^3/V \equiv y^3, \\ X &= M(4\pi/3)d^3/V_r = Y/(1-Y), \end{aligned} \right\} \quad (1)$$

where y stands for $d/D = Y^{1/3}$.

(1°) **Idealized States of the Adhesion:** From the microscopic view there are various interactions between the filler and the chain molecules on the surface of the particles. Some parts of the chain molecules around the particles are fixed on the surface of the filler loosely or tightly according to the type of adhesion. The term "adhesion" in this paper includes both physical attractions and chemical bonds. The actual state of adhesion is approximated by a mixture of two idealized states: the one is the ideal state (ideal state I) in which the medium adheres perfectly to the particles, and the other is the ideal state of perfect non-adhesion (ideal state II) in which the medium and the particles exhibit no interaction.

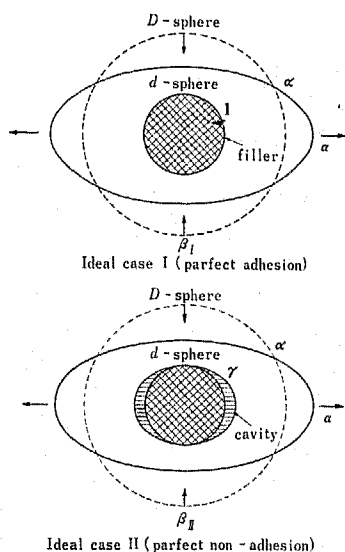

Fig.3 One-body approximation in terms of D-sphere.

Fig.4 A network chain around point P within rubbery medium in D-sphere.

(2°) **Internal Deformation:** In general the uniform external deformation α of the homogeneous materials is a transformation matrix by which any point P of the material with a position vector R with respect to an arbitrary origin transforms to the point P' with a vector R' , such as

$$R' = \alpha R. \quad (2)$$

Namely we assume that the internal deformation in the homogeneous materials is equivalent to the external one (the "requirement of proportionality"). But the internal deformation in the heterogeneous materials must be distinguished from the external or apparent one. Now the internal deformation α_R in the present theory is defined by the following formulae, with respect to the center of D -sphere taken as the origin

$$R' = \alpha_R R, \quad (3)$$

and

$$\alpha_R = \frac{D}{R} \frac{R-d}{D-d} \alpha + \frac{d}{R} \frac{D-R}{D-d} \gamma \quad (4)$$

$$= \alpha' - (D/R)\alpha'', \quad (4')$$

and α' , α'' imply that

$$\alpha' = (\alpha - \gamma\gamma)/(1 - \gamma), \quad \alpha'' = \{\gamma/(1 - \gamma)\}(\alpha - \gamma), \quad (4a)$$

where γ represents the transformation matrix in which the points of the inner surface of the rubbery medium facing the particles transforms to their deformed positions according to the external deformation α .

It can make sure easily that α_R satisfies the following conditions:

- (i) $\alpha_R = \alpha$ over the D -sphere.
- (ii) $\alpha_R = \gamma$ over the d -sphere.
- (iii) $\alpha_R \rightarrow \alpha$ as $Y \rightarrow 0$.

In addition to the above conditions, the following condition is necessary for the determination of γ :

- (iv) γ minimizes the free energy of the system under the external deformation α .

(As a matter of fact, the formula of α_R must be determined from the above conditions in opposition to this paper. Although more correct formula for α_R is obtained in this way, and more accurate theory is derived based on it, they are not touched upon in this paper).

(3°) **Shape and Size of the Cavity:** Let us consider the external deformation α of our specimen in simple elongation with the elongation ratio $\alpha_z = \alpha$ along the z -axis and the contraction ratio β along the x and y -axes:

$$\alpha = (\alpha_i \delta_{ij}) = \begin{pmatrix} \beta & 0 & 0 \\ 0 & \beta & 0 \\ 0 & 0 & \alpha \end{pmatrix}, \quad (5)$$

where δ_{ij} is Kronecker's delta

$$\delta_{ij} = \begin{cases} 1, & (\text{if } i=j), \\ 0, & (\text{if } i \neq j). \end{cases}$$

Now consider the matrix γ under the simple elongation. In the ideal state I, the adhesion holds despite of any external deformation of the specimen. While in the ideal state II, the parts of medium contacted with the filler slide over the particle surfaces smoothly or separate themselves from the surface freely according to the magnitude of the elongation ratio α , then the cavities are appearing on the both sides of each particle. The shape of the surface of the cavity is considered to resemble closely to an ellipsoid of revolution with minor axes (x and y -axes), d , and a major axis (z -axis), γd , ($1 \leq \gamma$), from the consideration of the axial symmetry. Therefore, the shape of the cavity is assumed to be the ellipsoid of revolution above mentioned, and then γ is an unknown function of α which is determined so as to minimize the free energy of deformation of the specimen under a constant elongation α .

Then the deformation of the cavity γ can be written as

$$\gamma = (\gamma_{ij}) = \begin{pmatrix} 1 & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & \gamma \end{pmatrix}. \quad (6)$$

To distinguish the quantities for two ideal states I and II, suffixes I and II will henceforth be appended to them respectively, and the quantities without suffix denote them in the general state. Thus we may now write

$$\gamma_I = \begin{pmatrix} 1 & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & 1 \end{pmatrix}, \quad \gamma_{II} = \begin{pmatrix} 1 & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & \gamma \end{pmatrix}, \quad (6')$$

or

$$\gamma_I = \mathbf{1}, \quad \gamma_{II} = \mathbf{1} + \epsilon, \quad (6'')$$

where $\mathbf{1}$ and ϵ are defined as follows:

$$\mathbf{1} = (\delta_{ij}) = \begin{pmatrix} 1 & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & 1 \end{pmatrix}, \quad \epsilon = \begin{pmatrix} 0 & 0 & 0 \\ 0 & 0 & 0 \\ 0 & 0 & \gamma - 1 \end{pmatrix}. \quad (6a)$$

By the comparison between γ_I and γ_{II} in Eq. (6''), γ in the general state may be represented by

$$\gamma = \mathbf{1} + \zeta \epsilon, \quad (0 \leq \zeta \leq 1), \quad (6''')$$

where ζ is a parameter depending on the nature of adhesion between the rubbery medium and the particles such as $\zeta = 0$ and $\zeta = 1$ correspond to the respective adhesion states of the ideal cases I and II.

(4°) **Mixing Approximation and Its Application:** For the purpose of representing the adhesion state in the general state an approximation of mixing is adopted, so that the general adhesion state is approximated by the one in the mixed system comprising idealized states of perfect adhesion and perfect non-adhesion with a mixing ratio $(1 - \zeta) : \zeta$, respectively, where ζ denotes a characteristic parameter corresponding to the adhesion state in question. According to the mixing approximation, the volume V' , the free energy $F(\alpha)$ and γ of the general specimen in the deformed state can be written as

Fig. 5 Schematic representation of change in degree of adhesion $(1-\zeta)$ with respect to α (as X is fixed) or to X (as α is fixed.)

$$V' = (1-\zeta)V_I' + \zeta V_{II}', \quad (7)$$

$$F(\alpha) = (1-\zeta)F_I(\alpha) + \zeta F_{II}(\alpha) \quad (8)$$

and

$$\begin{aligned} \gamma &= (1-\zeta)\gamma_I + \zeta\gamma_{II} \\ &= 1 + \zeta e. \end{aligned} \quad (*)$$

Naturally Eq. (*) is equivalent to the presumption on γ in Eq. (6''').

Moreover the surface densities of the network chain adhered on the surface of the particles in the ideal state I, $g_f^{(m)}$, and the general state, g_f , are given as

$$\begin{aligned} g_f &= (1-\zeta)g_f^{(m)} + \zeta \cdot 0 \\ &= g_f^{(m)}(1-\zeta), \end{aligned} \quad (9)$$

because the surface density in the ideal state II is 0. Since the mixing ratio $(1-\zeta)$ plays the role of the reduction ratio from $g_f^{(m)}$ to g_f , $(1-\zeta)$ is called the "degree of adhesion" hereafter. When the volume of rubbery medium V_r is kept constant, Eq. (7) becomes

$$\phi = 1 + Y(\gamma - 1)\zeta, \quad (10)$$

where

$$\phi = V'/V = \alpha\beta^2. \quad (10a)$$

(5°) **Deformation Theorem, Local Deformation:** Since the requirement of proportionality in the ordinary theory of rubber elasticity no longer holds validity for the heterogeneous system, it must be replaced by the deformation theorem of the network chains in our system. Consider a network chain in the D -sphere with end-to-end vector \mathbf{r} which is connecting a junction at the point \mathbf{R} to the other junction at $\mathbf{R} + \Delta\mathbf{R}$. By using the definition of internal

deformation in Eq. (3), (4'), the deformation can be derived in the following way:

$$\begin{aligned}\Delta R' &= \Delta(\alpha_R R) \\ &= \alpha_R \Delta R + (\Delta \alpha_R) R \\ &= \alpha_P \Delta R,\end{aligned}\tag{11}$$

or

$$r' = \alpha_P r,\tag{12}$$

where

$$\begin{aligned}\alpha_P &= \alpha_R + (D/R)\alpha''(ll), \\ (\alpha'' &= \{y/(1-y)\}(\alpha - \gamma)),\end{aligned}\tag{12a}$$

and $r' = \Delta R'$, $r = \Delta R$, also $l = R/R$, and (ll) denotes a dyadic with ij components $l_i l_j$ (Appendix A cf.). As a matter of course the deformation theorem in Eq. (12) becomes the requirement of proportionality in Eq. (2), when the concentration of the filler Y tends to 0. In the formulae (12), (12a), α_P is called the "local deformation" around the point P defined by R .

(6°) Arrangement of Main Assumptions: In the present consideration, the filler-reinforced rubber-like substance is considered as a double network model which is constructed both from the ordinary network chains in the medium with volume density g_r and from the adhered network chains over the particle surfaces with surface density $g_f = g_r^{(m)}(1-\zeta)$.

It is convenient to arrange the assumptions in the theory, about here:

- (a) Spherical particles are uniformly dispersed in the rubbery medium.
- (b) The movements of the center of each particle under the external deformation accords to the requirement of proportionality.
- (c) The one-body approximation in terms of D -sphere is adopted.
- (d) The adhesion state is represented by the mixing approximation.
- (e) The shape of the surface of cavity assumes the ellipsoid of revolution.
- (f) The volume of rubbery medium is kept constant.
- (g) The usual assumptions in the ordinary theory of rubber elasticity are adopted here except the requirement of proportionality: such as

(α) The network chains are Gaussian.

(β) The free energy of the system consists of two parts: the part by the sum of the entropy of individual chains and the liquid like interaction energy $U(\phi)$ among the segments ($U(\phi)$ is a function of ϕ only in Eq. (10), and is related with (f)).

3. ENERGY OF DEFORMATION OF DOUBLE NETWORK SYSTEM

The free energy of the system per unit initial volume $F(\alpha)$ under the external deformation may be divided into two parts: the volume energy $F_r(\alpha) + U(\phi)$ and the surface energy $F_f(\alpha)$, then

$$F(\alpha) = F_r(\alpha) + F_f(\alpha) + U(\phi).\tag{13}$$

Moreover the volume energy consists from the entropy part $F_r(\alpha)$ and the internal energy $U(\phi)$. The former is induced from the entropy of ordinary

network chains which are spatially distributed in rubbery medium with volume density g_r . The surface energy $F_f(\alpha)$ is induced from the entropy of adhered network chains whose ends in one side are distributed on the particle surface with surface density $g_f^{(m)}$ in the ideal state I.

As well known the entropy of a Gaussian chain with end-to-end vector r and N segments of each length a is represented by

$$\frac{3kT}{2Na^2}r^2, \quad (14)$$

where k is Boltzmann's constant and T is the absolute temperature. When the external deformation proceeds through $I \rightarrow \alpha$, the above entropy should increase in such a way

$$\begin{aligned} \frac{3kT}{2Na^2}r^2 &\longrightarrow \frac{3kT}{2Na^2}r'^2 \\ &= \frac{3kT}{2Na^2}(\alpha_P r \cdot \alpha_P r), \end{aligned} \quad (14')$$

because of $r \rightarrow r' = \alpha_P r$ according to the deformation theorem in Eq. (12).

(1°) **The Volume Energy of Deformation $\Delta F_v(\alpha)$:** The entropy part of the volume energy contained in a unit volume about a point P at the position R is given by

$$\sum_N g_N \frac{3kT}{2Na^2} \int (\alpha_P r \cdot \alpha_P r) f(r, N) dr, \quad (15)$$

where the quantity $f(r, N)$ is defined as the probability that one end of a network chain which consists of N segments with end-to-end vector r will be in the volume element dr when the other end is fixed at R , and g_N is the number of the network chains with N segments per unit volume of rubbery medium, then

$$g_r = \sum_N g_N. \quad (16)$$

Therefore, $F(\alpha)$ can be obtained by the integration of the entropy in Eq. (15) taken with respect to the medium of all D -sphere such as (Appendix B cf.)

$$\begin{aligned} F_r(\alpha) &= (M/V) \int \left[\sum_N g_N \left\{ \frac{3kT}{2Na^2} \right\} \int (\alpha_P r \cdot \alpha_P r) f(r, N) dr \right] dR \quad (17) \\ &= \{MG/(2V)\} \int_{(D)} \text{Tr.} (\tilde{\alpha}_P \alpha_P) dR \\ &= \frac{G}{2} \left\{ \left(I + \frac{y^2}{1-y} \right) I_{aa} - 2 \frac{y^2}{1-y} I_{ar} + y^2 \left(I + \frac{y^2}{1-y} \right) I_{rr} \right\}, \end{aligned} \quad (17')$$

where $G = g_r kT$, $\int_{(D)} \dots dR$ denotes the volume integral taken with respect to the rubbery medium in each D -sphere, $\tilde{\alpha}$ denotes the transpose matrix of α , and I_{AB} denotes

$$I_{AB} = \text{Tr.} (\mathbf{AB}) = \sum_{i,k} A_{ik} B_{ik} \quad (18)$$

for arbitrary matrices \mathbf{A} and \mathbf{B} , then

$$\left. \begin{aligned} I_{aa} &= \sum_i \alpha_i^2 = 2\beta^2 + \alpha^2, \\ I_{ar} &= \sum_i \alpha_i \gamma_i = 2\beta + \alpha\gamma_3, \\ I_{rr} &= \sum_i \gamma_i^2 = 2 + \gamma_3, \\ I_1 &= \text{Tr.} \mathbf{1} = 3. \end{aligned} \right\} \quad (18')$$

Hence the energy of deformation $\Delta F_r(\alpha)$ is defined as the increase in $F_r(\alpha)$ through the process of deformation $\mathbf{1} \rightarrow \alpha$, such as

$$\Delta F_r(\alpha) = F_r(\alpha) - F_r(\mathbf{1}).$$

When $\gamma_{\text{I}} = 1$ and $\gamma_{\text{II}} = \gamma$ are substituted in γ_3 in Eq. (17), we obtain

$$\Delta F_{r\text{I}}(\alpha) = \frac{G}{2} \left\{ \left(1 + \frac{y^2}{1-y} \right) (I_{aa} - I_1) - 2 \frac{y^2}{1-y} (I_a - I_1) \right\} \quad (19, 1)$$

and

$$\begin{aligned} \Delta F_{r\text{II}}(\alpha) &= \frac{G}{2} \left\{ \left(1 + \frac{y^2}{1-y} \right) (I_{aa} - I_1) - 2 \frac{y^2}{1-y} (I_{aa} - I_1) \right. \\ &\quad \left. + y^2 \left(1 + \frac{y^2}{1-y} \right) (I_{rr} - I_1) \right\}. \end{aligned} \quad (19, 2)$$

Using the mixing approximation, the relations $I_{ar} = I_a + I_{ar}$ and $I_{rr} = (\gamma^2 - 1)$, $F_r(\alpha)$ in the general state can be written as follows:

$$\begin{aligned} \Delta F_r(\alpha) &= (1 - \zeta) \Delta F_{r\text{I}}(\alpha) + \zeta \Delta F_{r\text{II}}(\alpha) \\ &= \frac{G}{2} \left\{ \left(1 + \frac{y^2}{1-y} \right) (I_{aa} - I_1) - 2 \frac{y^2}{1-y} (I_a - I_1) \right. \\ &\quad \left. - 2 \frac{y^2}{1-y} \alpha(\gamma - 1)\zeta + y^2 \left(1 + \frac{y^2}{1-y} \right) (\gamma^2 - 1)\zeta \right\} \end{aligned} \quad (19)$$

(2°) **The Surface Energy of Deformation $\Delta F_f(\alpha)$** : Similarly the surface energy per unit initial volume of the system in the deformed state $F_f(\alpha)$ can be calculated by almost the same way as in $F_r(\alpha)$ except $F_{f\text{II}}(\alpha) = 0$, because there are not any adhered chains over the surface of all particles in the ideal state II: $g_{f\text{II}} = 0$.

In this case the local deformation α_P in the ideal state I is reduced to the next form according to Eq. (12a)

$$[\alpha_P]_{\substack{r=1 \\ R=d}} = 1 + (\alpha - 1)(\mathbf{1}\mathbf{1})/(1 - y). \quad (20)$$

The surface energy per unit area on the surface of the particles is given by

$$\sum_N g_{fN}^{(m)} \frac{3kT}{2Na^3} \int [\alpha_P \mathbf{r} \cdot \alpha_P \mathbf{r}]_{\substack{r=1 \\ R=d}} f(\mathbf{r}, N) d\mathbf{r}, \quad (21)$$

hence $F_{f\text{I}}(\alpha)$ is given as the surface integral of above entropy over each

surface S of all particles in the system: (Appendix cf.)

$$F_{fI}(\alpha) = (M/V) \int \left[\sum_N g_{fN}^{(m)} \{ 3kT / (2Na^2) \} \int_{R=d}^{r=1} [\alpha_P r \cdot \alpha_P r] f(r, N) dr \right] dS \quad (22)$$

$$\begin{aligned} &= \frac{M4\pi d^2}{2V} g_f^{(m)} kT \frac{1}{3} \left\{ 3I_1 + \frac{2}{1-y} (I_a - I_1) + \frac{1}{(1-y)^2} (I_{aa} - 2I_a + I_1) \right\} \\ &= \frac{g_f^{(m)} kT}{2d} \frac{y^3}{(1-y)^2} \{ I_{aa} - 2yI_a + (3y^2 - 4y + 2)I_1 \}, \end{aligned} \quad (22')$$

where $g_{fN}^{(m)}$ denotes the surface density of the adhered network chains with N segments in the ideal state I, and hence $\sum_N g_{fN}^{(m)} = g_f^{(m)}$. As before

$$\Delta F_{fI}(\alpha) = \frac{g_f^{(m)} kT}{2d} \frac{y^3}{(1-y)^2} \{ (I_{aa} - I_1) - 2y(I_a - I_1) \} \quad (23)$$

is obtained. From the fact $\Delta F_{fII}(\alpha) \equiv 0$, we get

$$\begin{aligned} \Delta F_f(\alpha) &= (1-\zeta) \Delta F_{fI}(\alpha) + \zeta \Delta F_{fII}(\alpha) \\ &= \frac{G'}{2} \frac{y^3}{(1-y)^2} \{ (I_{aa} - I_1) - 2y(I_a - I_1) \}, \end{aligned} \quad (24')$$

here

$$G' = g_f^{(m)} (1-\zeta) kT/d \quad (24a)$$

is a surface modulus which is converted into the volume modulus equivalent to $G = g_r kT$.

(3°) **The Free Energy of Deformation $\Delta F(\alpha)$** : When $\Delta F_r(\alpha)$ in Eq. (19) and $\Delta F_f(\alpha)$ in Eq. (24') are substituted in Eq. (13), the free energy of deformation of the system $\Delta F(\alpha)$ can be derived as follows;

$$\begin{aligned} \Delta F(\alpha) &= (1/2) \{ A_\zeta (I_{aa} - I_1) - 2B_\zeta (I_a - I_1) \\ &\quad - 2C_\zeta I_{a(r-1)} \zeta + D_\zeta (I_{rr} - I_1) \zeta \} + \Delta U(\phi), \end{aligned} \quad (25)$$

where

$$\left. \begin{aligned} A_\zeta &= G \{ 1 + y^2/(1-y) + Ky^3/(1-y)^2 \}, \\ B_\zeta &= G \{ y^2/(1-y) + Ky^4/(1-y)^2 \}, \\ C_\zeta &= Gy^2/(1-y), \\ D_\zeta &= Gy^2 \{ 1 + y^2/(1-y) \}, \end{aligned} \right\} \quad (25a)$$

and

$$\begin{aligned} K &= K_o (1-\zeta), \\ K_o &= g_f^{(m)} / (g_r d). \end{aligned} \quad (25b)$$

It is a notable fact that the deformed state of the system cannot be determined only by $\Delta F(\alpha)$, but also by the following condition on the volume of the system as shown in a Eq. (10) ;

$$\phi = 1 + Y(\gamma - I) \zeta, \quad (10)$$

especially

$$\phi_{II} = I + Y(\gamma - I). \quad (10a)$$

(4°) **Stability of Deformation and Determination of Cavity:** The size of cavity is represented in term of γ or ϕ_{II} which is determined by the stability condition of the deformation in the ideal state II.

The determination equation of ϕ_{II} is obtained by the minimization of $\Delta F_{II}(\alpha)$ under the incidental condition in Eq. (10a).

Under the simple elongation $\alpha_1 = \alpha_2 = \beta$, $\alpha_3 = \alpha$, $\Delta F_{II}(\alpha)$ which is given by taking $\zeta = I$ in Eq. (25) and the incidental condition are written in these forms,

$$\begin{aligned} \Delta F_{II}(\alpha) &= \Delta F_{r,II}(\alpha) \\ &= (I/2)[A_1(\alpha^2 + 2\beta_{II}^2 - 3) - 2\beta_1(\alpha + 2\beta_{II} - 3) \\ &\quad - 2C_1\alpha(\gamma - I) + D_1(\gamma^2 - I)] + \Delta U(\phi_{II}) \end{aligned} \quad (26)$$

and

$$\phi_{II} = \alpha\beta_{II} = I + Y(\gamma - I). \quad (26a)$$

The condition for the stability as α being kept constant is given by

$$\left(\frac{\partial \Delta F_{II}}{\partial \beta_{II}} \right)_{\alpha, \gamma} = 0, \quad \left(\frac{\partial \Delta F_{II}}{\partial \gamma} \right)_{\alpha, \beta_{II}} = 0 \quad (27)$$

and it is written in the following formula:

$$\frac{A_1\beta_{II} - B_1}{C_1\alpha - D_1\gamma} = \frac{\alpha\beta_{II}}{Y}, \quad (27')$$

or using Eq. (25a) and Eq. (26a), it becomes

$$\begin{aligned} (I - y + y^2)\sqrt{\alpha}\sqrt{\phi_{II}^3} - \{y^3\sqrt{\alpha^3} + (I - y + y^2)(I - y^3)\sqrt{\alpha} \\ - y^4(I - y + y^2)/\sqrt{\alpha}\}\sqrt{\phi_{II}} - y^6 = 0. \end{aligned} \quad (27'')$$

From Eq. (27'') the next formula is derived

$$\phi_{II}'(I) = y^3 \frac{2(I + y - y^2)}{2(I - y + y^2)} \mp y^3 \frac{I + y - y^2}{I - y + y^2}$$

and it is to be used in next section.

4. TENSION AND YOUNG'S MODULUS

(1°) **Tension:** In the simple elongation $\alpha_1 = \alpha_2 = \beta$, $\alpha_3 = \alpha$, the internal pressure $p = -(\partial \Delta U / \partial V')$ is determined by the fact

$$\sigma_1 = \partial \Delta F / \partial \alpha_1 = 0 \quad \text{or} \quad \sigma_2 = \partial \Delta F / \partial \alpha_2 = 0.$$

Using this relation and Eq. (25), the tension $\sigma_3 = \sigma$ becomes

$$\sigma = (\partial \Delta F / \partial \alpha)_\beta$$

Fig. 6 An example for relation of tension *versus* elongation in filled rubber vulcanizates⁵⁾. Theoretical curves are calculated from Eq. (28').

$$= A\zeta(\alpha - \phi/\alpha^3) - B\zeta(1 - \sqrt{\phi/\alpha^3}) - (C\zeta/Y)(\phi - I), \quad (28)$$

or using Eq. (25a)

$$\begin{aligned} \sigma = G \left\{ 1 + \frac{y^2}{1-y} + K \frac{y^3}{(1-y)^2} \right\} \left(\alpha - \frac{\phi}{\alpha^2} \right) \\ - \left\{ \frac{y^2}{1-y} + K \frac{y^4}{(1-y)^2} \right\} \left(1 - \sqrt{\frac{\phi}{\alpha^3}} \right) - \frac{\phi - I}{y(1-y)}. \end{aligned} \quad (28')$$

The tension σ in Eq. (28') is divided into three parts: the volume effect which contains the volume concentration function $y^2/(1-y)$, the surface effect which contains the surface concentration function $y^3/(1-y)^2$ and the factor K , and the cavitation effect $(\phi - I)/\{y(1-y)\}$ which is the product of the volume function $y^2/(1-y)$ and the size of the cavity $(\gamma - I)\zeta = (\phi - I)/y^3$. When y tends to 0 in Eq. (28'), σ agrees with

$$\sigma = G(\alpha - 1/\alpha^2)$$

in usual theory.

As one of the example the comparison between the theoretical tension and the experimental one⁵⁾ is shown in Fig. 6.

(2°) **Initial Young's Modulus:** To obtain Young's modulus E at $\alpha = 100\%$, differentiating σ in Eq. (28') with respect to α , E can be calculated as follows:

$$\begin{aligned} E &= \left(\frac{\partial \sigma}{\partial \alpha} \right)_{\alpha=1} \\ &= 3(A\zeta - B\zeta/2) \{ 1 - \phi'(I)/3 \} - (C\zeta/Y) \phi'(I), \end{aligned}$$

or using the Eq. (25a) and $\phi'(I) = \zeta \phi_{II}'(I)$ in Eq. (10)

Fig. 7 Three effects and reinforcing tendency in Young's modulus.

$$\begin{aligned}
 E = E_0 \left[\left\{ 1 + \frac{1}{2} \frac{y^2}{1-y} \right\} (1 - \phi\zeta) \right. & \dots\dots\dots \text{(volume effect)} \\
 + K \frac{y^3 (1-y/2)}{(1-y)^2} (1 - \phi\zeta) & \dots\dots\dots \text{(surface effect)} \\
 \left. - \frac{y^2}{1-y} \frac{\phi\zeta}{y^3} \right], & \dots\dots\dots \text{(cavitation effect)}
 \end{aligned} \tag{29}$$

where

$$\begin{aligned}
 \phi &= \phi_{\pi}'(I)/3 \\
 &= \frac{y^3}{3} \frac{1+y-y^2}{1-y+y^2},
 \end{aligned} \tag{29a}$$

and E_0 is the initial Young's modulus in the ordinary theory;

$$E_0 = 3G.$$

It is clear that E tends to E_0 in the ordinary theory as y tends to 0.

As shown in Eq. (29), E is also divided into three effect, and they are shown in Fig. 7 schematically.

The theoretical view of the reinforcement in Young's modulus E with respect to several values for K_0 and $(1-\zeta)$ is shown in Fig. 8. There are various types of the reinforcing curves which range from the linear property to the curved one corresponding to our experience. As examples of the linear property and curved one, the measured curves for precipitated calcium carbonate filled natural rubber vulcanizate and silica filled one are shown in

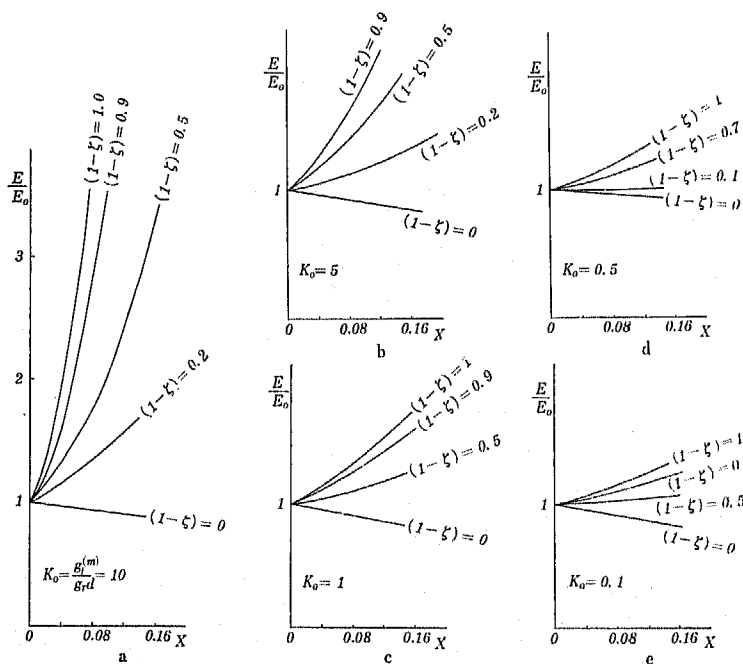

Fig. 8 Theoretical view of reinforcement in initial Young's modulus (calculated from Eq.(29)).

Fig. 9 a An example of linear reinforcing property in modulus.⁶⁾ Theoretical curves are calculated from Eq.(29)

Fig. 9 b An example of curved reinforcing property in modulus.⁶⁾ Theoretical curves are calculated from Eq.(29)

Fig. 9, a and b, respectively.⁶⁾

5. THREE EFFECTS AND INTERNAL MECHANISM OF FILLER REINFORCEMENT

Each quantity in the theory are divided into three parts which are the volume effect, the surface effect and the cavitation effect, as seen in σ and E . In general the volume effect has the volume modulus $G = g_r kT$ and a concentration function $y^2/(1-y)$, and the surface effect has the surface modulus $G' = g_f kT/d$ (converted volume one) and a concentration function $y^3/(1-y)^2$.

Fig. 10 Volume concentration function and surface concentration function in Young's modulus.

The concentration dependencies of filler reinforcement in the theory are determined through the volume concentration function $y^2/(1-y)$ due to the spatial distribution of the ordinary network chains within rubbery medium and the surface concentration function $y^3/(1-y)^2$ due to the surface distribution of the adhered one over the particles. Although the cavitation effect is influenced also through the volume function $y^2/(1-y)$, it's reason is understood that the cavitation effect due to the spatial distribution of the network chains in the cavity with volume density 0.

The volume concentration function $y^2/(1-y)$ increases almost linearly with filler concentration X in the wide range of $0 < X < 9$, (it is easily verified that $y^2/(1-y) \approx 3X$ for $0 < X < 9$), while the surface one $y^3/(1-y)^2$ increases very rapidly with increasing X , as shown in Fig. 10. Hence the linear property of the volume effect is clearer at the lower range of X , and the curved property of the surface

effect comes to have relative merit at the higher range of X . The curvature in the reinforcing curves increases or decreases in response to the magnitude of $K = g_f/(g_r d)$, ($g_f = g_f^{(m)}(1-\zeta)$) which is a ratio of the surface density g_f/d (converted volume one) to the volume density g_r of the network chains. Therefore K plays a role of an amplification factor of the surface effect which is relative to the volume effect.

It may be clear from the above consideration that the reinforcing behaviour of the every filler (not only the inert filler but also the active filler) can be understood in the whole aspect.

For example, let us see again the theoretical view of the reinforcing curves of E in Fig. 8.

6. SWELLING ELASTICITY AND CONDITION FOR SWELLING EQUILIBRIUM

In the swelling of the filler-reinforced heterogeneous specimen, the distinction between the internal swelling and the apparent (external) swelling is necessary. It is impossible to distinguish without having a theory based upon the heterogeneous character of the filled specimen,

(1°) **The Tension and Young's Modulus in Swollen State:** Let us consider the swollen deformed filled specimen in the equilibrium state with apparent deformation α' due to the solvent absorbed and the force externally applied.

Let us assume that the volumes of rubbery medium and solvent in the swollen deformed gel are additive. The volume of the specimen in the general adhesion state becomes

$$V' = V_r + M(4\pi/3)d^3\zeta_s + n_l V_l, \quad (30)$$

where n_l is the number of moles of solvent with molar volume V_l in the swollen medium and ζ_s denotes ζ in the swollen state. If the volume fraction of chain molecules within the swollen medium denotes v_2 , the internal swelling ratio is given by $1/v_2$:

For simplicity the process from the natural state to the above state is divided into the next two stages:

(i) Isotropic swelling process from the natural state to the state of external swelling ratio q^3 :

$$1 \longrightarrow \alpha_s = q1,$$

where the suffix s denotes the swollen quantities in general.

(ii) Deformation process without a volume change in the swollen medium

$$\alpha_s \longrightarrow \alpha' = \alpha\alpha_s = q\alpha,$$

where α is deformation due to the external applied forces.

In the first stage, the initial volume of specimen $V = M(4\pi/3)D^3$ is expanded to $V_s = q^3V = M(4\pi/3)D'^3$, where $D' = qD$. Then the concentration which sways the properties of the swollen specimen is not y , but y' defined as d/D' , and

$$\begin{aligned} y' &= d/D' = (d/D)(D/D') \\ &= y/q \quad (< y). \end{aligned} \quad (31)$$

Therefore the deformation theorem of the network chains in the swollen double-network system is obtained thus

$$r' = \alpha_p(y')r,$$

where $\alpha_p(y')$ is the local deformation in which y in Eq. (4) is replaced by y' .

The entropy part of deformation energy of the swollen system $\Delta F(\alpha')$ under the simple elongation is obtained in such a way, when the quantities α , ζ and y in Eq. (25) are substituted by α' , ζ_s and y' respectively, that

$$\Delta F_e(\alpha') = (1/2) \{ A_c'(\alpha'^2 + 2\beta'^2 - 3) - 2B_c'(\alpha' + 2\beta' - 3) - 2C_c'\alpha'(\gamma - 1)\zeta_s + D_c'(\gamma^2 - 1)\zeta_s \}, \quad (32)$$

where

$$A_c' = A_c(y'), \quad B_c' = B_c(y'), \quad \text{etc.}$$

in Eq. (25a).

The changes of free energy ΔF_1 and ΔF_2 in the processes $1 \rightarrow \alpha_s$ and $\alpha_s \rightarrow \alpha'$ are calculated in the following ways,

(i) $1 \rightarrow \alpha_s$: (taking account of non-cavitation: $\gamma = 1$):

$$\begin{aligned} \Delta F_1 &= [\Delta F_e(y', \alpha_s) - \Delta F_e(y, 1)]_{\gamma=1} \\ &= (3/2) \{ A_c'(q^2 - 1) - 2B_c'(q - 1) \}. \end{aligned} \quad (33)$$

(ii) $\alpha_s \rightarrow \alpha' = \alpha\alpha_s$: (take care that $\alpha' = q\alpha$, $\beta' = q\beta$ in Eq. (32))

$$\begin{aligned} \Delta F_2 &= \Delta F_e(y', \alpha') - \Delta F_1 \\ &= (1/2) \{ A_c' \{ q^2(\alpha^2 + 2\beta^2) - 3 \} - 2B_c' \{ q(\alpha + 2\beta) - 3 \} \\ &\quad - 2C_c' q\alpha(\gamma - 1)\zeta_s + D_c'(\gamma^2 - 1)\zeta_s \} \\ &\quad - (1/2) \{ A_c'(3q^2 - 3) - 2B_c'(3q - 3) \} \\ &= (1/2) \{ q^2 A_c'(\alpha^2 + 2\beta^2 - 3) - 2qB_c'(\alpha + 2\beta - 3) \\ &\quad - 2qC_c'\alpha(\gamma - 1)\zeta_s + D_c'(\gamma^2 - 1)\zeta_s \}. \end{aligned} \quad (34)$$

Then the change of free energy $\Delta F_s(\alpha)$ per unit swollen volume in the whole process can be written thus,

$$\begin{aligned} \Delta F_s &= (V/V') \Delta F_2 = q^{-2} \Delta F_2 \\ &= (q^{-2}/2) \{ q A_c'(\alpha^2 + 2\beta^2 - 3) - 2B_c'(\alpha + 2\beta - 3) \\ &\quad - 2C_c'\alpha(\gamma - 1)\zeta_s + q^{-1} D_c'(\gamma^2 - 1)\zeta_s \} + \Delta U(\phi_s), \end{aligned} \quad (35)$$

where ϕ_s is the volume condition corresponding to the process (ii) defined as

$$\begin{aligned} \phi_s &= V/V_s = \alpha\beta^2 \\ &= 1 + Y'(\gamma - 1)\zeta_s. \end{aligned} \quad (36)$$

From the above equations the tension σ_s and Young's modulus E_s in the swollen state are obtained in a similar way as in σ and E ;

$$\begin{aligned} \sigma_s &= Gq^{-2} \left[q \left\{ 1 + \frac{y'^2}{1-y'} + K_s \frac{y'^3}{(1-y')^2} \right\} \left(\alpha - \frac{\phi_s}{\alpha_2} \right) \right. \\ &\quad \left. - \left\{ \frac{y'^2}{1-y'} + K_s \frac{y'^4}{(1-y')^2} \right\} \left(1 - \sqrt{\frac{\phi_s}{\alpha^3}} \right) - \frac{\phi_s - 1}{y'(1-y')} \right] \end{aligned} \quad (37)$$

and

$$\begin{aligned} E_s &= 3Gq^{-2} \left[q \left\{ 1 + \frac{y'^2}{1-y'} + K_s \frac{y'^3}{(1-y')^2} \right\} \right. \\ &\quad \left. - \frac{1}{2} \left(\frac{y'^2}{1-y'} + K_s \frac{y'^4}{(1-y')^2} \right) \right] (1 - \phi_s \zeta_s) - \frac{\phi_s \zeta_s}{y'(1-y')}, \end{aligned} \quad (38)$$

where

$$K_s = K_0(1 - \zeta_s), \quad (K_0 = g_f^{(m)} / (g_s d))$$

and

$$\phi_s = \frac{y'^3}{3} \frac{(-q^{-1} + qy')(1 - y' + y'^2) + 3}{\{q^{-1}(2 + y'^3) + qy'^4\}(1 - y' + y'^2) - y'^3}. \quad (38a)$$

As a matter of course if the concentration $y = y'q$ tends to 0, σ_s and E_s become σ and E respectively in the ordinary theory;

$$\sigma_s \rightarrow \sigma = Gv_2^{1/3}(\alpha - 1/\alpha^2), \quad (\text{as } y \rightarrow 0)$$

and

$$E_s \rightarrow E = E_0v_2^{1/3}, \quad (\text{as } y \rightarrow 0).$$

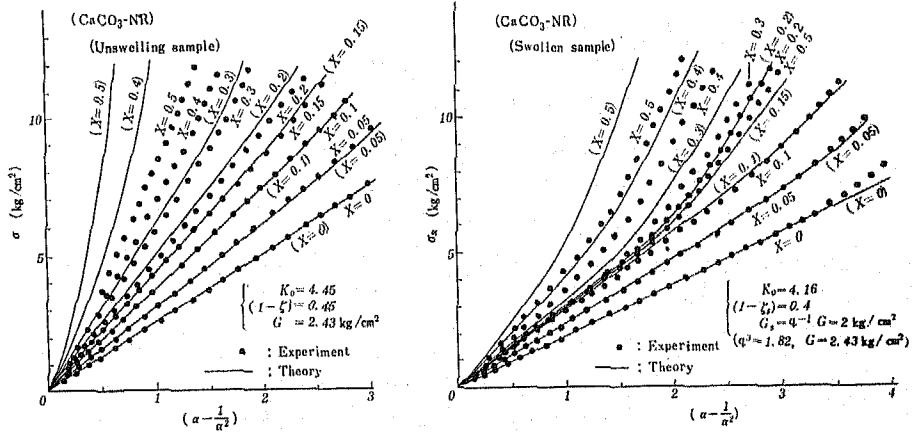

Fig. 11 Comparison between tension σ and swelling tension σ_s .
Theoretical curves are calculated from Eqs.(28') and (37) respectively.

The comparison between the theory and the experiment³⁾ is shown in Fig. 11 for σ and σ_s over a wider range ($0 \leq X \leq 0.5$) than one in Fig. 6. For the specimens of higher concentration $X = 0.4, 0.5$, the experimental curves lie far under the theoretical ones. It can be understood that the treatment of $(1 - \zeta) = \text{constant}$ (Fig. 5 cf.) adopting here becomes unsuitable at such a high concentration range, because of the excess of local deformation. The theoretical view of the swelling effect on Young's modulus E is shown in Fig. 12.

(2°) **The Equilibrium Condition in Free Swelling:** Let the specimen be immersed in the solvent, and it is invaded by the liquid molecules until the initial volume V increases to the equilibrium one $V_s = q^3 V$ without an external force applied in the isothermal process.

Fig. 12 Comparison between initial Young's modulus E in unswelling state and E_s in swollen state. (calculated from Eqs. (29) and (38))

From the equations (30) and (33), the swelling ratio q^3 and the energy of deformation ΔF_e of the system in this case can be written as follows,

$$q^3 = 1 + n_l V_l / V, \quad (39)$$

and

$$\Delta F_e = (3/2)V \{ A_c'(q^2 - 1) - 2B_c'(q - 1) \}. \quad (33')$$

Using these equations, we get

$$\begin{aligned} \frac{\partial \Delta F_e}{\partial n_l} &= \frac{\partial \Delta F_e}{\partial q} \frac{\partial q}{\partial n_l} \\ &= V_l q^{-2} (A_c' q - B_c'). \end{aligned} \quad (40)$$

As well known the invasion of the liquid molecules into the rubbery medium owes to the decreasing nature in the free energy of mixing ΔF_m , while the invasion of the liquid brings about the increase of the elastic energy ΔF_e stored in extending double network system due to swelling. The condition for equilibrium with respect to the invasion of liquid is that, for a small variation δn_l moles of the liquid content, the decrease $(\partial \Delta F_m / \partial n_l) \delta n_l$ in ΔF_m is canceled with the increment $(\partial \Delta F_e / \partial n_l) \delta n_l$ in ΔF_e . In other words the free energy of the system $\Delta F = \Delta F_m + \Delta F_e$ is minimized with respect to n_l :

$$\frac{\partial \Delta F}{\partial n_l} = \frac{\partial \Delta F_m}{\partial n_l} + \frac{\partial \Delta F_e}{\partial n_l} = 0. \quad (41)$$

Fig. 13 An example of reinforcement in unswelling Young's modulus and resistance to swelling in benzene.⁶⁾ Theoretical curves are calculated from Eqs.(28') and (43)

Using Eq.(40) and the Flory-Huggins expression for $\partial \Delta F_m / \partial n_l$ such that

$$\frac{\partial \Delta F_m}{\partial m_l} = RT \{ \log (1 - v_2) + v_2 + \mu v_2^2 \}, \quad (42)$$

the equilibrium condition in Eq.(41) becomes

$$\log (1 - v_2) + v_2 + \mu v_2^2 + \frac{V_1 G}{RT} q^{-2} \left[q \left\{ 1 + \frac{y'^2}{1 - y'^2} + K_s \frac{y'^3}{(1 - y')^2} \right\} - \left\{ \frac{y'^2}{1 - y'} + K_s \frac{y'^4}{(1 - y')^2} \right\} \right] = 0, \quad (43)$$

where μ is the Huggins coefficient.

As an example, the modulus $E' = \{ \sigma / (\alpha - 1/\alpha^2) \}_{\alpha=2}$ in the unswollen state and swelling ratio q^3 are compared with those calculated from Eq. (28') and Eq. (43) as shown in Fig. 13. The same specimens are used in both experiments.⁶⁾

CONSIDERATION OF GENERALIZED SURFACE ENERGY AND SURFACE LAYER

(1°) **The Theory Taking Account of the Surface Energies besides ΔF_f :** When the surface of the cavity is extending, several kinds of surface energies induced by the various molecular mechanisms in addition to ΔF_f , may appear, if we consider in detail.

Although such energies cannot be estimated similarly as the energy of the external surface in the ordinary theory of rubber elasticity, the phenomenological treatment of the surface energies of cavity is not always difficult in the present theory.

In general, the surface energy of any kind is proportional to the surface area in question and the every surface force is a function of that area.

In the present theory the total surface area of the cavity $S(\gamma)$ under the external deformation α is written as

$$S(\gamma) = M2\pi d^2 \{ 1 + (\gamma / \sqrt{1 - 1/\gamma^2}) \sin^{-1} \sqrt{1 - 1/\gamma^2} \}, \quad (44)$$

then the resultant surface force $\Gamma(\gamma)$ based on the various energies is a function of γ . Therefore, the work $H(\gamma)$ done during the extension of the surface from $S(1)$ to $S(\gamma)$ becomes

$$H(\gamma) = \int_1^\gamma \Gamma(\gamma) dS(\gamma), \quad (45)$$

and it must be added to the $\Delta F(\alpha)$ in Eq. (25). Let $\Delta F^*(\alpha)$ be the energy of deformation of the system in this case and it is given by

$$\begin{aligned} \Delta F^*(\alpha) &= \Delta F + H(\gamma) \\ &= (1/2) \{ A_c(\alpha^2 + 2\beta^2 - 3) - 2B_c(\alpha + 2\beta - 3) \\ &\quad - 2C_c\alpha(\gamma - 1)\zeta + D_c(\gamma^2 - 1)\zeta \} + \Delta U(\phi) + H(\gamma). \end{aligned} \quad (46)$$

From this $\Delta F^*(\alpha)$ and the condition on the volume in Eq. (10) the tension σ^* in this case is obtained in the same way as before,

$$\begin{aligned} \sigma^* &= G \left[\left\{ 1 + \frac{y^2}{1-y} + K \frac{y^3}{(1-y)^2} \right\} \left(\alpha - \frac{\phi}{\alpha^2} \right) \right. \\ &\quad \left. - \left\{ \frac{y^2}{1-y} + K \frac{y^4}{(1-y)^2} \right\} \left(1 - \sqrt{\frac{\phi}{\alpha^3}} \right) - \frac{\phi - 1}{y(1-y)} \right]. \end{aligned} \quad (47)$$

Although σ^* does not differ from the previous tension σ in Eq. (28') formally, but the determinate equation for γ namely

$$\frac{A_c\beta_{II} - B_c}{C_c\alpha - D_c\gamma - \frac{\partial H}{\partial \gamma}} = \frac{\alpha\beta_{II}}{Y} \quad (48)$$

differs from the previous one in Eq. (27') only a term $\partial H/\partial \gamma$.

(2°) **On the Surface Layer Covering the Particles:** The state and the structure of the boundary of filler to rubbery medium is not clear at present. However, many investigators believe that there are perhaps some degenerated layers consisting of rubber vulcanizates around the surface of the filler with finite thickness.

Such a layer surrounding a dispersed particle may be described in terms of some simplifying picture, e. g., the following picture is considered: the overcuring layer enclosing each d -sphere with the thickness δ and the volume density $g_i(R)$ around the position R . Perhaps $g_i(R)$ may be a decreasing continuous function at $d \leq R < d + \delta$, having a limiting value of $\lim_{R \rightarrow d+\delta} g_i(R) = g_r$.

In this case, the analysis requires increases in the number of observables, e. g., not only $g_i(R)$ but also δ appears as additional parameter in this picture.

At least if one of those informations is inaccurate, the theory based upon such a model falls into a mere speculation because of the excess in parameters. Actually the thickness of the boundary layer may not be defined without the precise data.

Such being the case, let us avoid the detailed discussion concerned with the structure and the state of the boundary layer at present.

Nevertheless, if the dispersion structure within the specimen in question is suitable to a picture with δ and $g_l(R)$ above mentioned, the present theory may remain valid, more or less, according to the actual state, by using of the converted surface density:

$$\bar{g}_f = \frac{1}{d'^{1/2}} \int_d^{d+\delta} g_l(R) R^2 dR, \quad (49)$$

where d' is a suitable parameter having some value in the range $d < d' < d + \delta$. But the above method is not so desirable.

APPENDIX

A. Deformation Theorem of Network Chains: The definition of the internal deformation in Eq. (3) is written again

$$R' = \alpha_R R, \quad (A1)$$

where

$$\alpha_R = \alpha' - (D/R)\alpha'' \quad (A2)$$

and

$$\alpha' = (\alpha - y\alpha)/(1-y), \quad \alpha'' = \{y/(1-y)\}(\alpha - \gamma). \quad (A3)$$

Taking the increment ΔR in R about the point P, the equation (A1) becomes

$$\begin{aligned} \Delta R' &= \Delta(\alpha_R R) \\ &= \alpha_R (\Delta R) + (\Delta \alpha_R) R \\ &= \alpha_R (\Delta R) + \{d(\alpha_R)/dR\} \Delta R R \\ &= \alpha_R (\Delta R) + (D/R^2) \alpha'' (\Delta R R). \end{aligned} \quad (A4)$$

As seen in Fig. 4, the following relations are clear

$$R = RI, \quad \Delta R = \Delta R \cdot I.$$

According to the above relations the i -component $\Delta R X_i$ of a factor $\Delta R R$ in Eq. (A4) can be written as the following form

$$\begin{aligned} \Delta R X_i &= \left(\sum_{j=1}^3 \Delta X_j l_{ij} \right) (l_i R) \\ &= R \sum_{j=1}^3 (l_i l_{ij}) \Delta X_j, \end{aligned}$$

or in the vector form

$$\Delta R R = R(I I) \Delta R. \quad (A5)$$

Then the factor $\Delta R R$ in Eq. (A4) is replaced by this relation, the local deformation α_P and the deformation theorem are so obtained that

$$\begin{aligned} \Delta R' &= \alpha_R \Delta R + (D/R) \alpha'' (I I) \Delta R \\ &= \{ \alpha_R + (D/R) \alpha'' (I I) \} \Delta R, \end{aligned}$$

Fig. 14 Illustration of spherical coordinate systems (R, Θ, Φ) and (r, θ, φ) .

can be written,

$$dR = R^2 \sin \Theta d\Theta d\Phi \quad (B1)$$

and

$$dr = r^2 \sin \theta d\theta d\varphi. \quad (B2)$$

Remember the definition of the probability $f(r, N)dr$ in the section 3 and since the network chains in the system are Gaussian and have the isotropic distribution with respect to r , $f(r, N)dr$ can be written such that

$$f(r, N)dr = f_N w_N(r) r^2 \sin \theta dr d\theta d\varphi, \quad (B3)$$

where

$$w_N(r) = \{3/(2\pi Na^2)\}^{3/2} \exp\{-3r^2/(2Na^2)\}, \quad (B4)$$

$$f_N = g_N/g_r, \text{ (Eq. (16) cf.)}. \quad (B5)$$

The next relation is necessary in our calculation;

$$\begin{aligned} & \int (\alpha_P r \cdot \alpha_P r) f(r, N) dr \\ &= \text{Tr.} (\alpha_P \alpha_P) \int (rr) f(r, N) dr = (Na^2/3) f_N \text{Tr.} (\alpha_P \alpha_P). \end{aligned} \quad (B6)$$

To prove this relation, let k be the direction cosine of r , the next calculation is performed such that

$$\begin{aligned} & \int (\alpha_P r \cdot \alpha_P r) f(r, N) dr = \int \text{Tr.} (\alpha_P \alpha_P) (rr) f(r, N) dr \\ &= \text{Tr.} (\alpha_P \alpha_P) \int (rr) f(r, N) dr \end{aligned}$$

$$r' = \alpha_P r, \quad (A6)$$

where $r' = \Delta R'$, $r = \Delta R$ and

$$\alpha_P = \alpha_R + (D/R) \alpha''(ll). \quad (A7)$$

B. On the Calculation of Volume

Energy: Now consider the spherical coordinate system of two kinds (R, Θ, Φ) and (r, θ, φ) in a D -sphere as illustrated in Fig. 14. It is to be noticed that z' -axis is taken in the same direction of elongation axis, and the origin P (defined as a vector R) of the coordinate system (r, θ, φ) moves within the whole rubbery medium in the D -sphere as the integration in Eq. (17) is taken in the D -sphere.

The each volume elements around R and r in those coordinate systems

$$\begin{aligned}
&= \text{Tr.} (\alpha_P \alpha_P) f_N \left[\int_0^\infty r^2 w_N(r) 4\pi r^2 dr \right] \left\{ (1/4\pi) \int_0^{2\pi} \int_0^\pi (\mathbf{k} \mathbf{k}) \sin \theta d\theta d\varphi \right\} \\
&= f_N (Na^2/3) \text{Tr.} (\alpha_P \alpha_P),
\end{aligned}$$

but the well known relation

$$\int_0^\infty (r^2) w_N(r) 4\pi r^2 dr = Na^2 \quad (\text{B7})$$

and the relation

$$\begin{aligned}
&\frac{1}{4\pi} \int_0^{2\pi} \int_0^\pi (\mathbf{k} \mathbf{k}) \sin \theta d\theta d\varphi \\
&= \frac{1}{4\pi} \int_0^\pi \sin \theta d\theta \int_0^{2\pi} \begin{pmatrix} \sin^2 \theta \cos^2 \varphi & \sin^2 \theta \sin \varphi \cos \varphi & \sin \theta \cos \theta \cos \varphi \\ \sin^2 \theta \cos \varphi \sin \varphi & \sin^2 \theta \sin^2 \varphi & \sin \theta \cos \theta \sin \varphi \\ \sin \theta \cos \theta \cos \varphi & \sin \theta \cos \theta \sin \varphi & \cos^2 \theta \end{pmatrix} d\varphi \\
&= \frac{1}{4\pi} \int_0^\pi \begin{pmatrix} \pi \sin^2 \theta & 0 & 0 \\ 0 & \pi \sin^2 \theta & 0 \\ 0 & 0 & 2\pi \cos^2 \theta \end{pmatrix} \sin \theta d\theta \\
&= \frac{1}{3} \begin{pmatrix} 1 & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & 1 \end{pmatrix} \quad (\text{B8})
\end{aligned}$$

are used in the above calculation.

In this connection, the following relation is equivalent to Eq. (B8)

$$\int (\mathbf{l} \mathbf{l}) d\Omega = (4\pi/3) \mathbf{1}, \quad (\text{B9})$$

where $d\Omega$ is the solid angle such as $d\Omega = \sin \theta d\theta d\varphi$.

By using of the equations (B6), (A7), (A2), (A3), and (B9), now the entropy part of the volume energy $F_r(\alpha)$ of the system per unit initial volume in Eq. (17) can be calculated in the following way,

$$\begin{aligned}
F_r(\alpha) &= (M/V) \int g_r d\mathbf{R} \sum_N \{3kT/(2Na^2)\} \int \text{Tr.} (\alpha_P \alpha_P)(r) f(r, N) dr \\
&= (M/V) g_r \int \text{Tr.} (\alpha_P \alpha_P) d\mathbf{R} \left[\sum_N f_N \{3kT/(2Na^2)\} (Na^2/3) \right] \\
&= \{M g_r kT/(2V)\} \int \text{Tr.} (\alpha_P \alpha_P) d\mathbf{R} \\
&= \{MG/(2V)\} \text{Tr.} \int_d^D R^2 dR \int [\alpha' \alpha' + 2(D/R) \{\alpha' \alpha' (\mathbf{l} \mathbf{l}) - \alpha' \alpha''\} \\
&\quad + (D^2/R^2) \{\mathbf{l} \mathbf{l} \alpha'' \alpha'' (\mathbf{l} \mathbf{l}) - 2\alpha'' \alpha'' (\mathbf{l} \mathbf{l}) + \alpha'' \alpha''\}] d\Omega
\end{aligned}$$

$$\begin{aligned}
&= \{MG/(2V)\} (4\pi/3) \text{Tr.} \int_d^D R^2 \{3\alpha'^2 - 4(D/R)\alpha'\alpha'' + 2(D^2/R^2)\alpha''^2\} dR \\
&= \{M4\pi D^3/(2V)\} (G/2) \text{Tr.} \{(1-y^3)\alpha'^2 - 2(1-y^2)\alpha'\alpha'' + 2(1-y)\alpha''^2\} \\
&= \{G/2(1-y)\} \{(1-y+y^2)I_{aa} - 2y^2I_{ar} + y^2(1-y+y^2)I_{rr}\}, \quad (\text{B10})
\end{aligned}$$

but the relations $V=M(4\pi/3)D^3$, $G=g_r kT$ and $d/D=y$ are used in the midst of the above calculation.

Taking $\gamma=1$ or $\gamma=\gamma$ in Eq. (B10), $\Delta F_{rI}(\alpha)$ or $\Delta F_{rII}(\alpha)$ is obtained at once.

C. On the Calculation of Surface Energy: Similarly the surface energy $F_{fI}(\alpha)$ of the system per unit initial volume in the ideal state I is calculated. (Remember that $\Delta F_{fII}(\alpha)=0$). Taking $\gamma=1$ and using $d/D=y$ in Eq. (A7), the local deformation at the surface of d -sphere in the ideal state I is reduced such that

$$[\alpha_P]_{r=1} = 1 + y^{-1}\alpha''(ll). \quad (\text{C1})$$

Using the equations (B6), (C1) and (A3) and an abridgement $[\] = [\alpha_P \alpha_P]_{r=1}^{R=d}$,

$F_{fI}(\alpha)$ can be calculated as

$$\begin{aligned}
F_{fI}(\alpha) &= (M/V) \int dS \sum_N \{3kT/(2Na^2)\} \int \text{Tr.} [\] (rr) g_f^{(m)} f(r, N) dr \\
&= (M/V) (g_f^{(m)} kT/2) \int d^2 d\Omega \text{Tr.} [\] \\
&= \{Md^2 g_f^{(m)} kT/(2V)\} \text{Tr.} \int [\] \{1 + 2y^{-1}\alpha''(ll) + y^{-2}\alpha''\alpha''(ll)\} d\Omega \\
&= \{M4\pi d^2/V\} (g_f^{(m)} kT/2) (1/3) \text{Tr.} \{31 + 2y^{-1}\alpha'' + y^{-2}\alpha''^2\} \\
&= \frac{g_f^{(m)} kT}{2d} y^3 \left\{ 3I_1 + \frac{2}{1-y} (I_a - I_1) + \frac{1}{(1-y)^2} (I_{aa} - 2I_a - I_1) \right\}. \quad (\text{C2})
\end{aligned}$$

It is notable that the specific surface area of the filler per unit volume of the specimen $M4\pi d^2/V=s$ appears at the midst of Eq. (C2), and it is so rewritten that

$$\begin{aligned}
s &= M4\pi d^2/V \\
&= (3/d)y^3, \quad (\text{C3})
\end{aligned}$$

because of $V=M(4\pi/3)D^3$. According to Eq. (C2), the surface effect in the filler reinforcement is proportional to the specific area s or inversely proportional to the mean diameter d under the constant concentration.
