The manuscript ID is CENE-D-21-00430R1.</p>

We thank you and the reviewers for your thoughtful suggestions and insights. The manuscript has benefited from these insightful suggestions. I look forward to working with you and the reviewers to move this manuscript closer to publication in *Clinical and Experimental Nephrology*.

The manuscript has been rechecked and the necessary changes have been made in accordance with the reviewers' suggestions. The responses to all comments have been prepared and attached herewith. The revisions are marked by single underlining with red font in the revised manuscript.

Thank you for your consideration. I look forward to hearing from you.

Sincerely,
Yuji Kamijo, M.D., Ph.D.

Responses to the reviewers' comments

We thank the reviewers for their valuable comments. We have revised the manuscript in accordance with the comments. The changes in the revised manuscript are marked by single underlining with red font.

Our responses to the reviewers' comments as given below.

Reviewer #1: Comment to the authors:

The manuscript is very nicely revised.

I would like to ask authors one more thing. The reviewer recommends to present Supplemental Figure 2 in the main text (not as supplemental material). I am sure that including the pictures of on-site evaluation greatly increase the impact to the readers. Additionally, please indicate glomeruli in the picture by arrows and add the explanations in the Figure legend.

Thank you for your valuable comment. We have moved Supplemental Figure 2 to Figure 2 shown in the main text. In addition, we have added arrows to the representative glomeruli among structures evaluated as glomeruli.

Reviewer #2: The manuscript has been modified to make it easier for the reader to understand.

It might be helpful to clarify that the authors evaluated ti (total inflammation) scores, not i (inflammation) scores for the Banff classification.

In supplemental figure 2, it is better to add arrows to the area evaluated as glomerulus.

Thank you for your valuable comment. We have added the explanation for the evaluation of the extent of interstitial inflammation, as described below.

"The extent of interstitial inflammation was evaluated as ti (total inflammation) scores rather than i (inflammation) scores, which was indicated by the Banff classification [15]."

We have added arrows to the representative glomeruli among structures evaluated as glomeruli in Figure 2 (modified Supplemental Figure 2).

19 **Abstract**

20 **Background:** On-site evaluation of fresh kidney biopsy (FKB) samples at the time of biopsy is
21 useful to verify that adequate specimens are acquired. However, some cases present poor correlation
22 between glomerular number in FKB samples and light microscopy (LM) samples. We examined the
23 usefulness of such on-site evaluation.

24 **Methods:** We conducted a retrospective cross-sectional observational study (n = 129) to assess the
25 correlation between glomerular number in FKB samples and LM samples and the associated factors
26 hindering the evaluation.

27 **Results:** There was a significant positive correlation between glomerular number in FKB samples
28 and LM samples. The median ratio of glomerular number (LM samples/FKB samples) was 0.74.
29 According to this ratio, cases were divided into three groups: reasonable estimation (65 cases),
30 underestimation (32 cases), and overestimation (32 cases). Comparing the reasonable and
31 underestimation groups, significant differences were detected in the extent of interstitial fibrosis and
32 tubular atrophy (IFTA) and interstitial inflammation. Logistic regression analysis demonstrated that
33 IFTA and interstitial inflammation were significantly associated with the underestimation. Moreover,
34 the cortex length of FKB samples correlated with glomerular number in LM samples regardless of
35 tubulointerstitial lesions.

42 **Keywords:** kidney biopsy, procedure, on-site evaluation, glomerular number, microscopy, tissue
43 analysis

1
2
3 **45 Introduction**
4
5

6 46 Evaluation of the pathological findings of kidney biopsy specimens is important for the diagnosis of
7
8
9 47 and decisions on the management of kidney diseases [1]. Biopsied kidney tissue should contain the
10
11
12 48 kidney cortex and an appropriate number of glomeruli. Kidney biopsy tissue is divided into three
13
14
15
16 49 portions, for light microscopy (LM), immunofluorescence (IF), and electron microscopy (EM)
17
18
19 50 analyses, and each portion should contain glomeruli [2]. Therefore, on-site evaluation at the time of
20
21
22 51 kidney biopsy is useful for acquiring adequate specimens [1, 3–7]. However, renal pathological
23
24
25 52 specimens may contain glomeruli even when glomeruli are not detected by on-site evaluation [8],
26
27
28 53 and there have been cases with poor correlation between glomerular number in fresh kidney biopsy
29
30
31
32 54 (FKB) samples and LM samples. In such cases, there is concern that the kidney needle pass number
33
34
35 55 will unnecessarily increase, or inadequate number of glomeruli will be obtained because of
36
37
38 56 underestimation or overestimation of results. Consequently, the following issues should be resolved:
39
40
41 57 1) the adequacy of the assessment of glomerular number in FKB samples and 2) the possible
42
43
44 58 associated factors that affect the evaluation of glomerular number in FKB samples. Herein, we
45
46
47
48 59 addressed these points to facilitate obtaining an adequate glomerular number from kidney biopsy.

9 **63** This was a single-center cross-sectional observational study. All cases (n = 151) who underwent
10
11
12 **64** ultrasonography-guided kidney biopsy at the Department of Nephrology, Shinshu University
13
14
15
16 **65** Hospital (Matsumoto, Japan) between November 2018 and May 2020 were enrolled. Patients who
17
18
19 **66** were younger than 20 years (6 cases) were excluded. Patients who received a 1-h biopsy after kidney
20
21
22 **67** transplantation (9 cases) were also excluded since this kidney biopsy procedure was different from
23
24
25
26 **68** that performed for other cases. Similarly, cases with insufficient data (7 cases) were excluded.
27
28
29 **69** Finally, 129 kidney samples from 122 patients were analyzed (Figure 1). In cases of multiple kidney
30
31
32 **70** biopsies of the same patient, each biopsy was treated as an independent kidney biopsy case. Five
33
34
35 **71** patients underwent kidney biopsy twice, and one patient underwent kidney biopsy three times. All
36
37
38 **72** procedures involving human participants were performed in accordance with the ethical standards of
39
40
41 **73** the Institutional Review Board of the Ethical Committee at Shinshu University School of Medicine
42
43
44 **74** (approval number: 4431) and with the 1964 Declaration of Helsinki and its later amendments or
45
46
47 **75** comparable ethical standards. The requirement of written informed consent was waived because of
48
49
50
51 **76** the retrospective nature of the study.

79 albumin, blood urea nitrogen, and creatinine levels; estimated glomerular filtration rate (eGFR) by
80 creatinine; [9] eGFR by cystatin C; [10] β 2-microglobulin, hemoglobin, and platelet counts;
81 hemoglobin A1c (HbA1c) levels; and urinary findings, such as protein, β 2-microglobulin, and *N*-
82 acetyl- β -D-glucosaminidase levels] recorded at the time of kidney biopsy were obtained from
83 medical records. History of smoking was also obtained. Hypertension was defined as the use of
84 blood-pressure-lowering drugs and/or blood pressure \geq 140/90 mmHg. Diabetes mellitus was defined
85 as the use of insulin or anti-diabetic drugs or HbA1c level \geq 6.5%. Dyslipidemia was defined as the
86 use of statins and/or low-density lipoprotein cholesterol levels \geq 140 mg/dl. Kidney biopsy
87 information included needle pass number, core number, total core length, glomerular number, cortex
88 percentage, cortex length, total division length for IF and EM, percentage of total division length to
89 total core length, experience of the clinical physician who performed the on-site evaluation, and
90 serious complications. The glomerular number and cortex percentage in FKB samples were
91 evaluated prior to the division of sample for IF and EM. The cortex length of FKB samples was
92 calculated by multiplying the cortex percentage by the total core length. Serious complications were
93 defined as conditions that required unplanned treatment.

94
95 **Kidney Biopsy Procedure**

96 Kidney biopsy was performed in accordance with the methods described in previous reports [1, 3, 4]

97 and in a Japanese guidebook [11]. One nephrologist performed a percutaneous kidney biopsy with an
98 automatic biopsy needle with ultrasound guidance. HI VISION Preirus (Hitachi Medical
99 Corporation, Tokyo, Japan) was used as the ultrasonic device, and a BARD MONOPTY (C.R. Bard,
100 Inc., New Jersey, USA) instrument with a gauge size of 16 and a needle length of 160 mm was used
101 as the automatic biopsy needle. The collected FKB samples were placed on a glass slide and
102 prevented from drying out by briefly immersing in a small amount of normal saline. Another
103 nephrologist performed an on-site evaluation of the FKB samples as quickly as possible. The
104 evaluation was performed with a standard light microscope adjusted to appropriate magnification
105 and light source. The core length was measured by placing the glass slide with the core on a graph
106 paper (Supplemental Figure 1). A representative picture of FKB samples visualized with a standard
107 light microscope is presented in [Figure 2](#). Glomeruli were recognized as circular structures with a
108 color tone different from that of the surroundings ([Figure 2a](#)). The nephrologist performing the on-
109 site evaluation apportioned the FKB samples for IF and EM according to the glomerular and cortex
110 localization. Each length for the IF or EM portion was 1–2 mm. Both nephrologists came to a
111 comprehensive decision on when to discontinue the needle passes based on the evaluation of FKB
112 samples and the clinical situation.

115 Total core length, glomerular number, cortex percentage, cortex length, glomerular sclerosis
116 percentage, crescent formation percentage, presence of glomerular hypertrophy, extent of interstitial
117 fibrosis and tubular atrophy (IFTA), extent of interstitial inflammation, presence of tubulitis,
118 presence of arteriolar hyalinosis, and presence of arterial intimal fibrosis were evaluated by LM,
119 with reference to previous reports [12, 13]. In addition, the presence of glomeruli in the IF and EM
120 specimens was evaluated. The cortex length of LM samples was calculated by multiplying the cortex
121 percentage by the total core length. Glomerular sclerosis percentage was defined as the total
122 percentage of global sclerosis and segmental sclerosis of the glomeruli. Glomerular hypertrophy was
123 defined as a glomerular diameter $\geq 250 \mu\text{m}$. The extent of IFTA and interstitial inflammation was
124 evaluated separately. These lesions were represented by the percentage of the lesion area in relation
125 to all the cortical area, and these areas were measured using ImageJ [14]. The extent of interstitial
126 inflammation was evaluated as ti (total inflammation) scores rather than i (inflammation) scores,
127 which was indicated by the Banff classification [15]. Each extent was also classified into four
128 categories as follows: none < 5%, 5% \leq mild < 25%, 25% \leq moderate < 50%, and 50% \leq severe.
129 Glomerular and vascular lesions were mainly evaluated by periodic acid–Schiff staining and periodic
130 acid–methenamine silver staining; tubulointerstitial lesions were evaluated by hematoxylin and eosin
131 staining and Masson trichrome staining. Besides the main renal pathologist, another renal pathologist
132 evaluated the renal pathological findings.

134 **Statistical Analysis**

135 Continuous variables are presented as the median and interquartile range, and categorical variables

136 are presented as numbers (n) and percentages (%). Continuous variables were compared using

137 Mann–Whitney *U*-test, and categorical variables were compared using Fisher’s exact test.

138 Correlations were evaluated using Spearman’s rank correlation coefficient.

139 Based on the interquartile range of the glomerular number ratio (LM samples/FKB samples), all

140 cases were divided into three groups: reasonable estimation group, i.e., cases within the interquartile

141 range; underestimation group, i.e., cases within the third quartile or higher; and overestimation

142 group, i.e., cases within the first quartile or lower. Although $P < 0.05$ was generally considered to

143 indicate statistical significance, in situations involving multiple comparisons (comparison of the

144 underestimation and reasonable estimation groups and of the overestimation and reasonable

145 estimation groups), $P < 0.025$ was the significance threshold. Associated factors hindering the

146 evaluation of glomerular number were examined by univariate and multivariate logistic regression

147 analyses adjusted for age and sex. All analyses were performed using IBM SPSS Statistics software

148 package version 26 for Windows (IBM Co., Ltd., New York, NY, USA).

151 **Results**

152 Patient's background, laboratory data and a part of renal pathological findings are presented in
153 Supplemental Table 1. Of the 129 kidney biopsy cases, 29 (22.5%) underwent kidney allograft
154 biopsies. Sixty-seven (51.9%) patients were male, and the median age of the patients was 49 years.
155 The most common pathological diagnosis was IgA nephropathy (22.5%). Information of FKB
156 samples and LM samples is shown in Table 1. The median needle pass number, core number, total
157 core length, glomerular number, cortex percentage and cortex length in FKB samples were 2, 2, 25
158 mm, 29, 90%, and 21 mm, respectively. The median total division length for IF and EM was 2.0 mm,
159 and the median percentage of total division length to total core length was 8.7%. Serious
160 complications occurred in two patients (1.6%), with both requiring blood transfusion. Pathological
161 findings evaluated by LM showed that the median glomerular number was 22. Glomeruli were
162 observed in the IF and EM specimens in almost all cases (98.4%). The median ratio of the
163 glomerular number in LM samples/FKB samples was 0.74 (0.48–0.97). The glomerular number in
164 FKB and in LM samples showed a significant positive correlation ($r = 0.398$, $P < 0.001$) (Figure 3).
165 Based on the interquartile range of the glomerular number ratio, 65 cases were assigned to the
166 reasonable estimation group, 32 cases to the underestimation group, and 32 cases to the
167 overestimation group (Table 1). Comparison of the reasonable estimation and underestimation
168 groups revealed significant differences in the extent of IFTA (15% vs. 30%, respectively, $P = 0.003$)

169 and interstitial inflammation (10% vs. 20%, respectively, $P = 0.001$). This suggested that the IFTA
170 and/or interstitial inflammation area were more pronounced in the underestimation group than those
171 in the reasonable estimation group. The number of needle passes in the underestimation group
172 tended to be higher than that in the reasonable estimation group ($P = 0.03$). Comparison of the
173 reasonable estimation group with the overestimation group revealed significant differences in the
174 cortex length of LM samples (16 mm vs. 12 mm, respectively, $P = 0.015$) (Table 1). Logistic
175 regression analysis demonstrated that the extent of IFTA and interstitial inflammation was
176 significantly associated with the underestimation of glomerular number (odds ratio, 1.031, $P =$
177 0.002, and odds ratio, 1.043, $P = 0.002$, respectively), while no factors were significantly associated
178 with the overestimation of glomerular number (Table 2 and Supplemental Table 2). Multivariate
179 logistic regression analysis adjusted for age and sex demonstrated that the extent of IFTA and
180 interstitial inflammation was significantly associated with the underestimation of glomerular number
181 (odds ratio, 1.035, $P = 0.001$, and odds ratio, 1.044, $P = 0.001$, respectively) (Table 3).
182 The cases were divided into two groups based on the extent of IFTA or interstitial inflammation: the
183 none and mild group ($n = 75$ and $n = 96$, respectively) and the moderate and severe group ($n = 54$
184 and $n = 33$, respectively). As shown in Figure 4a, there was a significant positive correlation
185 between the glomerular number in FKB and that in LM samples ($r = 0.608$, $P < 0.001$) when the
186 extent of IFTA was $<25\%$ (none and mild group). No correlation was observed when the extent of

187 IFTA was $\geq 25\%$ (moderate and severe group) (Figure 4b). Similarly, a significant positive
188 correlation, with a correlation coefficient of 0.556 ($P < 0.001$), was observed when the extent of
189 interstitial inflammation was $< 25\%$, but no correlation was observed when the extent of interstitial
190 inflammation was $\geq 25\%$ (Figure 4c, 4d).

191 In a previous study [5], the cortex length in LM samples was positively correlated with glomerular
192 number in LM samples. We reconfirmed this relationship ($r = 0.576$, $P < 0.001$) and found a high
193 correlation between cortex length of LM and FKB samples ($r = 0.865$, $P < 0.001$) (Supplemental
194 Figure 2); therefore, we examined the possibility of cortex length of FKB samples as an alternative
195 method for estimating the glomerular number in LM samples. Cortex length in FKB samples was
196 positively correlated to glomerular number in LM samples ($r = 0.485$, $P < 0.001$) (Figure 5a), and
197 this correlation was not affected by the degree of tubulointerstitial lesions (Figure 5b, 5c, 5d, 5e).

200 **Discussion**

201 We investigated the adequacy of the assessment of glomerular number in FKB samples for
202 estimation of glomerular number of LM samples, as well as the factors hindering this relationship.
203 The findings clarify the usefulness and provide important points to note when on-site evaluation is
204 performed.
205 We detected a significant positive correlation between glomerular number in FKB samples and LM
206 samples. Ferrer et al. [5] and Sekulic and Crary [7] reported that more adequate kidney tissue
207 samples could be obtained with on-site microscopic evaluation at the time of kidney biopsy than
208 without it. However, the authors did not assess this finding or the specifics of the evaluation in FKB
209 samples. Here, based on the comparison of glomerular number in FKB samples and LM samples, the
210 rationale for the efficacy of on-site microscopic evaluation at the time of kidney biopsy was
211 demonstrated. We report, for the first time, that the glomerular number determined in FKB samples
212 is greater than that determined in LM samples. This finding is reasonable because the FKB sample is
213 cut for IF and EM analyses and sliced during preparation of LM samples. Furthermore, we are the
214 first to show that the median ratio of the glomerular number in LM samples/FKB samples was 0.74.
215 With the multiplication of the glomerular number in FKB samples and this ratio, it is possible to
216 estimate the glomerular number in LM samples, when kidney biopsy is performed with the
217 procedure similar to that in this study. This information can be useful for obtaining the targeted

218 number of glomeruli in LM samples. Conversely, this ratio can be used to estimate the target number
219 of glomeruli in FKB samples for obtaining desired number of glomeruli in LM samples. The target
220 number of glomeruli in FKB samples is estimated to be 1.35 (1/0.74)-times the target number of
221 glomeruli in LM samples. For observing 20 glomeruli under LM, observation of over 27 glomeruli
222 in FKB samples would be recommended. However, we should note that this conversion ratio would
223 be strongly affected by the tubulointerstitial situation.

224 Although the relationship between glomerular number in the FKB samples and LM samples was
225 significant, the correlation coefficient was not very high. Some associated factors resulting in the
226 underestimation or overestimation of the glomerular number impacted the value of the correlation
227 coefficient. Factors associated with the underestimated value, namely, the extent of IFTA and
228 interstitial inflammation, were statistically detected here for the first time. The light source of the
229 light microscope makes FKB samples translucent and facilitates visual recognition of glomeruli [8].

230 We speculate that tubulointerstitial lesions may impair the translucency of FKB samples. According
231 to a previous study, decreased glomerular blood flow makes it difficult to visually recognize the
232 glomeruli in FKB samples [8]. However, a significant difference in glomerular blood flow-related
233 factors, including glomerular disease type, glomerular sclerosis percentage, glomerular hypertrophy,
234 arteriolar hyalinosis, and arterial intimal fibrosis, was not apparent. The current findings suggest that
235 tubulointerstitial lesions, such as IFTA and/or interstitial inflammation, are the major factors

1
2
3 236 hindering the recognition of glomeruli in FKB samples. Since IFTA and interstitial inflammation
4
5
6 237 lesions overlapped in most of the cases, we could hardly determine the major factor causing
7
8
9 238 underestimation. There was only one case of tubulointerstitial nephritis in which interstitial
10
11
12 239 inflammation was clearly predominant (the extent of interstitial inflammation being 80% and that of
13
14
15 240 IFTA being 40%). This case had a low glomerular number ratio (LM samples/FKB samples) of 0.31
16
17
18 241 and belonged to the overestimation group, suggesting that a significant underestimation factor might
19
20
21
22 242 be IFTA rather than interstitial inflammation.
23
24
25 243 A major clinical problem resulting from the underestimation results is an increase in unnecessary
26
27
28 244 kidney biopsy needle passes. In fact, the number of needle passes in the underestimation group
29
30
31 245 tended to be higher than that in the reasonable estimation group. When kidney biopsies are
32
33
34 246 conducted in cases where tubulointerstitial lesions are strongly expected, we should consider the
35
36
37 247 possibility that glomeruli may be present even if they are not confirmed in FKB samples, and avoid
38
39
40 248 excessive unnecessary kidney biopsy needle passes.
41
42
43 249 Assessment prior to kidney biopsy for possibility of the underestimation would be useful for clinical
44
45
46 250 physician. We demonstrate that tubulointerstitial lesions strongly influence the glomerular number
47
48
49 251 estimate. Previous studies have indicated that tubulointerstitial lesions deteriorate upon eGFR
50
51
52 252 decline and proteinuria [16, 17]. Therefore, serum and/or urinary markers reflecting kidney
53
54
55 253 dysfunction and/or tubulointerstitial injuries may predict the underestimation. However, individual
56
57
58
59
60
61
62
63
64
65

1
2
3 254 serum or urinary markers, including serum creatinine levels, eGFR, proteinuria, urinary β 2-
4
5
6 255 microglobulin, or urinary *N*-acetyl- β -D-glucosaminidase, were not significantly associated with the
7
8
9 256 underestimation. The possibility of severe tubulointerstitial lesions may need to be evaluated by total
10
11
12 257 assessment, keeping in mind the clinical course and various laboratory data.
13
14
15
16 258 The current study also demonstrates a significant positive correlation between the cortex length in
17
18
19 259 FKB samples and glomerular number in LM samples ($r = 0.485, P < 0.001$), which was not affected
20
21
22 260 by the degree of tubulointerstitial lesions (Figure [5a](#)). Ferrer et al. [5] reported that the cortex length
23
24
25 261 in LM samples is positively correlated with glomerular number as shown in the current study ($r =$
26
27
28 262 $0.576, P < 0.001$) (Supplemental Figure [2a](#)); however, they did not report the correlation between the
29
30
31 263 cortex length of FKB samples and glomerular number in LM samples. We suggest that the cortex
32
33
34
35 264 length of FKB samples could be used as an alternative method for estimating the glomerular number
36
37
38 265 in LM samples, and this result appear to be useful when severe tubulointerstitial lesions are predicted
39
40
41 266 before kidney biopsy, or when glomeruli are difficult to recognize in the cortical region of FKB
42
43
44 267 samples. In the cases in which tubulointerstitial lesions were not severe, the cortex length of FKB
45
46
47 268 samples weaker correlated to glomerular number in LM samples, compared to glomerular number in
48
49
50 269 FKB samples, suggesting more clinical importance of on-site evaluation of glomerular number in
51
52
53
54 270 FKB samples.
55
56
57 271 The logistic regression analyses detected no factors significantly associated with the overestimation

272 results; however, Table 1 indicates that the cortex length of LM samples in overestimation group was
273 significantly shorter compared with that in reasonable estimation group. The cortex length of LM
274 samples is thought to be affected by the cortex length of FKB samples, the total division length for
275 IF and EM, and the percentage of total division length with respect to the total core length. These
276 factors did not differ significantly among the estimation groups; however, the cortex length of FKB
277 samples tended to be short and same length of division was performed in the overestimation group,
278 which might result in the shorter cortex length of LM samples and lower glomerular number. These
279 findings suggest that overestimation group consists of the cases with a shorter cortex in LM samples
280 via the loss of large cortex area due to division for IF and EM.

281 We used a standard light microscope that is routinely used at the authors' institution. Currently, there
282 is no consensus whether on-site evaluation microscope should be a standard light microscope or a
283 dissecting microscope. Previous studies involved the use of a standard light microscope only [6], a
284 dissecting microscope only [4, 7], or either [1, 3]. It is generally considered that these microscopes
285 do not significantly affect the on-site evaluation because they are the same type of light microscope
286 using visible light and lens system. Although it was reported that a standard light microscope can be
287 used for a more facile and rapid visualization of glomeruli than a dissecting microscope [8], not
288 enough evidence is available to support this notion. The efficacy of using a standard light
289 microscope and that of a dissecting microscope should be compared to resolve this.

290 The current study has several limitations. First, the number of needle passes was determined not only
291 by the need to obtain glomeruli, but also by the clinical situation, such as bleeding. It was, therefore,
292 difficult to determine if the underestimation group tended to have more needle passes due to
293 underestimation results. Second, this study was a single-center study; therefore, verification of the
294 results, and their generalization, in other facilities is needed. Since the kidney biopsy procedure has
295 been standardized according to previous reports and Japanese guidebooks, the results of the current
296 study may be applicable to any facility performing kidney biopsy [1, 3, 4, 11]. Third, the sample size
297 was small, and it is possible that the confounding factors were not fully adjusted for multivariate
298 analysis. Fourth, the interobserver reproducibility of the on-site evaluation and the influence of the
299 experience of the on-site evaluation physician were not evaluated in any of the cases in the current
300 study. However, the data for eight cases in which two nephrologists performed on-site evaluation
301 suggested that the results of on-site evaluation did not differ significantly between evaluation
302 physicians and no particular tendency was observed depending on their experience (Supplementary
303 Table 3). To reduce the possible effect of the evaluation physician's experience, the on-site
304 evaluation in the current study was performed by different physicians with various years of
305 experience. As a result, we did not detect a major influence of the evaluation physician's experience
306 on underestimation or overestimation results.

307 In conclusion, a significant positive correlation between the glomerular number in FKB samples and

308 LM samples was detected. The glomerular number determined by on-site microscopic evaluation at
309 the time of kidney biopsy can be used to estimate the actual glomerular number in LM samples,
310 suggesting the clinical benefit of on-site microscopic evaluation. However, tubulointerstitial lesions,
311 such as IFTA and/or interstitial inflammation, may make it difficult to recognize glomeruli in FKB
312 samples. In cases with severe potential tubulointerstitial lesions, the possibility of glomerular
313 number underestimation should be considered, and the appropriate timing of the discontinuation of
314 kidney biopsy should be decided by other information. In such cases, evaluation of cortex length of
315 FKB samples may substitute for evaluating glomeruli on-site.

364 **Figure Legends**

365 **Fig. 1** Flow diagram of the inclusion and exclusion criteria in the current study

366

367 **Fig. 2** Fresh kidney biopsy (FKB) samples as seen with a standard light microscope.

368 (a) Kidney cortex containing the glomeruli which are circular structures with a different color tone

369 from the surroundings. The arrows indicate representative glomeruli among structures evaluated as

370 glomeruli. (b) Kidney medulla showing reddish vasculature but no glomeruli.

371

372 **Fig. 3** Relationship between glomerular number in fresh kidney biopsy (FKB) samples and light

373 microscopy (LM) samples. The Spearman's rank correlation coefficient is 0.398 ($P < 0.001$). The

374 gray circles indicate cases in the reasonable estimation group, the blue inverted triangles represent

375 the underestimation group, and the red triangles represent the overestimation group. The solid lines

376 represent the regression line. The dashed line indicates the same values on the X- and Y-axes

377

378 **Fig. 4** Relationship between glomerular number in FKB samples and LM samples stratified by

379 tubulointerstitial damage lesions. (a) Cases with the extent of interstitial fibrosis and tubular atrophy

380 (IFTA) of less than 25%. The Spearman's rank correlation coefficient is 0.608 ($P < 0.001$). (b) Cases

381 with the extent of IFTA of 25% or more. The Spearman's rank correlation coefficient is 0.159 ($P =$

400 **Supplemental Figure Legends**

401 **Supplemental Fig. 1** Fresh kidney biopsy (FKB) samples on a glass slide placed on a graph paper.

402

403 **Supplemental Fig. 2** Analyses concerning cortex length of light microscopy (LM) samples.

404 (a) Relationship between cortex length of LM samples and glomerular number in LM samples. The
405 Spearman's rank correlation coefficient is 0.576 ($P < 0.001$). (b) Relationship between cortex length
406 in fresh kidney biopsy (FKB) samples and that in LM samples. The Spearman's rank correlation
407 coefficient is 0.865 ($P < 0.001$). The gray circles indicate cases in the reasonable estimation group,
408 the blue inverted triangles represent the underestimation group, and the red triangles represent the
409 overestimation group. The solid line represents the regression line.

423 **Table 3.** Multivariate analysis of the association of IFTA or interstitial inflammation with the
424 underestimation or overestimation results

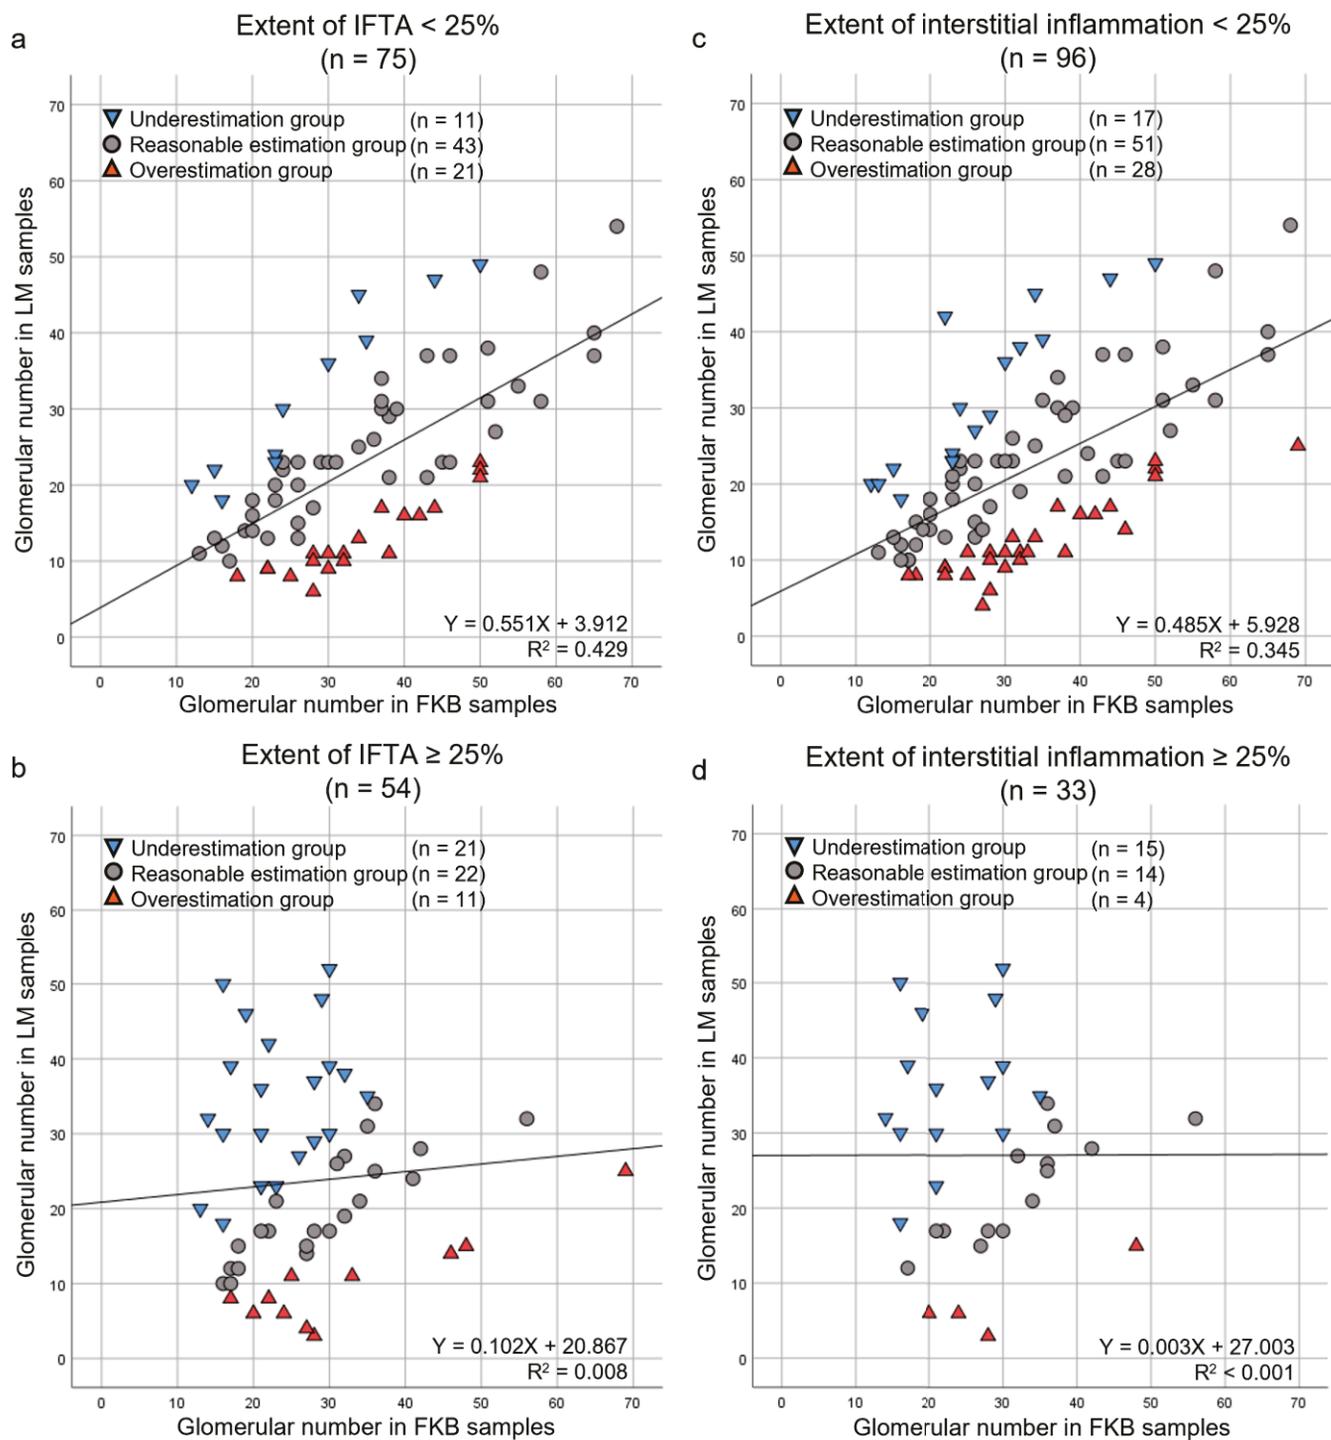

Model		Underestimation			Overestimation		
		Odds ratio	95% CI	<i>P</i>	Odds ratio	95% CI	<i>P</i>
1	Extent of IFTA (%)	1.031	1.011–1.052	0.002*	0.987	0.962–1.012	0.29
2	Extent of IFTA (%)	1.035	1.013–1.056	0.001*	0.983	0.957–1.010	0.23
3	Extent of interstitial inflammation (%)	1.043	1.016–1.070	0.002*	1.002	0.973–1.032	0.88
4	Extent of interstitial inflammation (%)	1.044	1.017–1.073	0.001*	1.002	0.972–1.032	0.92

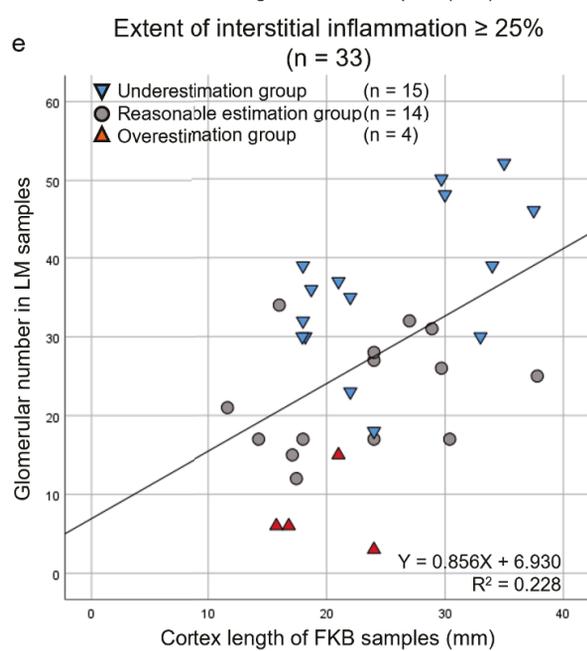

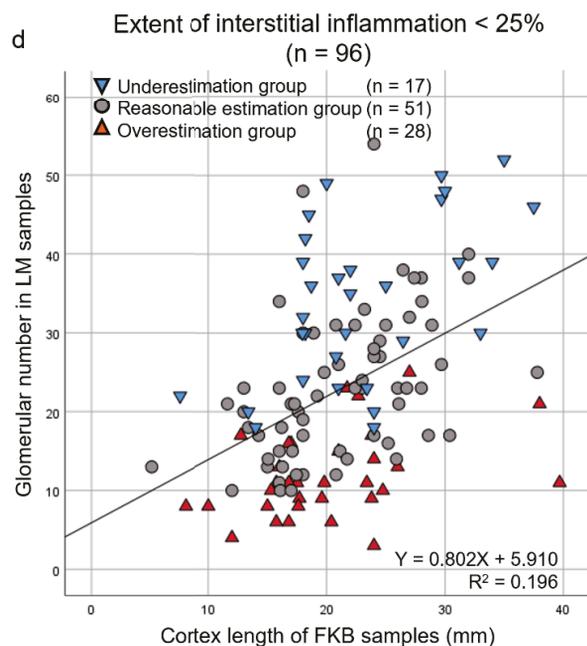

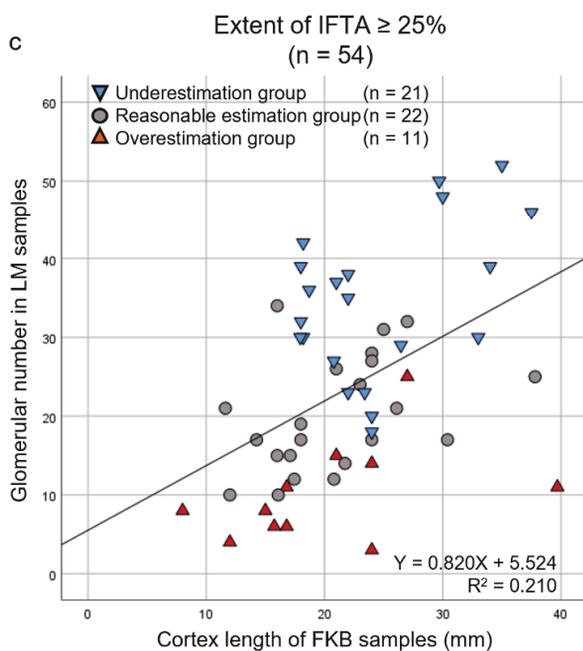

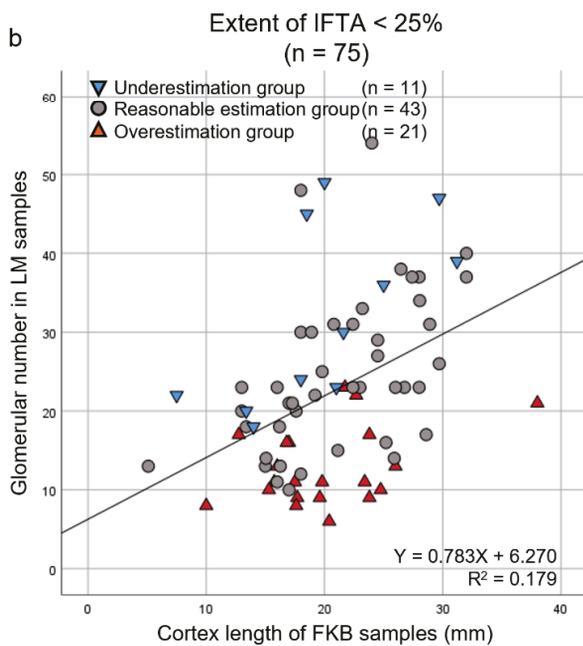

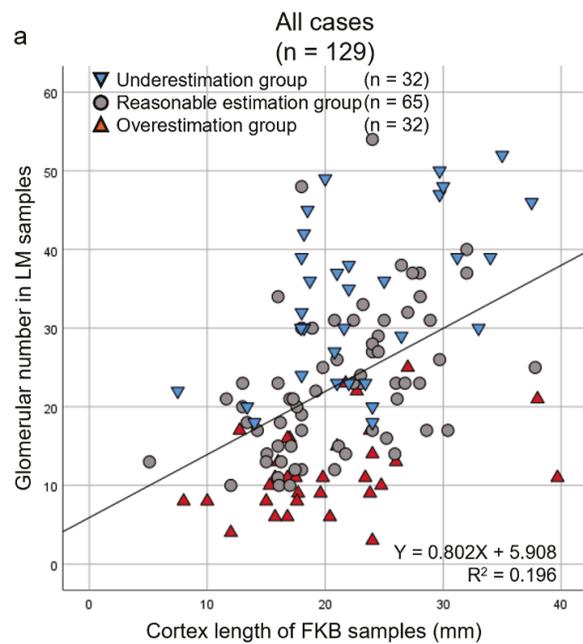

425 Multivariate logistic regression analysis was performed. Model 1,3 is an unadjusted model. Model
426 2,4 is adjusted for age and sex.
427 CI, confidence interval; IFTA, interstitial fibrosis and tubular atrophy. * *P* < 0.025.

Prerequisites for Publication

Authorship: The Editors of *Clinical and Experimental Nephrology* adhere to recommendations of the International Committee of Medical Journal Editors [<http://www.icmje.org>] regarding criteria for authorship.

Accordingly, each person listed as an author or coauthor for a submitted report must meet all three criteria. An author or coauthor shall have:

1. Conceived, planned, and performed the work leading to the report, or interpreted the evidence presented, or both;
2. Written the report or reviewed successive versions and participated in their revision;
3. Approved the final version.

Meeting these criteria should provide each author with sufficient knowledge of and participation in the work to allow him or her to accept public responsibility for the report.

Certification: This Certification Form should be signed and submitted with the manuscript. The senior or corresponding author is requested to certify that all listed individuals qualify for authorship according to the above three criteria. The author (s) should also certify that: no part of the work described has been published before; that the work is not under consideration for publication elsewhere; that if and when the manuscript is accepted for publication, the author(s) agree to automatic transfer of the copyright to the society and that the manuscript, or its parts, will not be published elsewhere subsequently in any language without the consent of the copyright holders.

The Certification Form must be uploaded as a scanned file (PDF, TIFF, or JPEG) on the online system, Editorial Manager.

Animal and human research: Research involving humans must be carried out in accordance with the ethical standards of the responsible committee (institutional or regional) or with the Helsinki Declaration of 1964 and all subsequent revisions.

Studies involving animal experimentation must include a statement of compliance with the guidelines as recommended by the Science Council of Japan or the National Research Council's criteria (NIH No. 86-23).

Certification Form – To be submitted with manuscript to *Clinical and Experimental Nephrology*

Manuscript title: Glomerular Number Assessment in Fresh Renal Tissue and Pathological Specimens

I/We hereby certify that the work submitted is in full accordance with the statement of "Prerequisites for Publication" for *Clinical and Experimental Nephrology*.
