## Abstract

**Background/Aims:** Primary biliary cirrhosis (PBC) is an organ-specific autoimmune disease of still unidentified genetic etiology that is characterized by chronic inflammation of the liver. Since *cytotoxic T-lymphocyte antigen 4 (CTLA4)* polymorphisms have recently been linked with PBC susceptibility in studies on Caucasians, we investigated the genetic association between *CTLA4* polymorphisms and PBC in a Japanese population.

**Methods:** Five single nucleotide polymorphisms (SNPs) in the *CTLA4* gene (rs733618, rs5742909, rs231775, rs3087243, and rs231725) were genotyped in 308 patients with PBC and 268 healthy controls using a TaqMan assay.

**Results:** One *CTLA4* gene SNP (rs231725) was significantly associated with susceptibility to anti-mitochondrial antibody (AMA)-positive PBC, but clinical significance disappeared after correction for multiple testing. Moreover, *CTLA4* gene SNPs did not influence AMA development or disease progression to orthotopic liver transplantation in our Japanese cohort. In haplotype analyses, one haplotype [haplotype 1 (CGGA)] at rs5742909, rs231775, rs3087243, and rs231725, was significantly associated with susceptibility to both AMA-positive PBC and overall PBC.

**Conclusions:** This study showed that *CTLA4* gene polymorphisms had a modest,

1  
2  
3  
4  
5 but significant, association with susceptibility to PBC in the Japanese population. The  
6  
7  
8 connection between genetic variants and function of the *CTLA4* gene remains to be  
9  
10  
11 addressed in future investigations.

## 1. Introduction

Primary biliary cirrhosis (PBC) is a liver-specific autoimmune disease characterized by female preponderance and destruction of intrahepatic bile ducts that often results in cirrhosis and hepatic failure [1]. The etiology of PBC has yet to be conclusively elucidated, although genetic factors are considered to play a prominent role in family and population studies [2-5]. Prior reports have shown the HLA-*DRB1\*08* allele to be a weak and regional determinant of PBC susceptibility [6-8]. However, HLA alone does not explain the entire genetic predisposition to PBC, mainly since at least 80 to 90% of patients with the disease do not carry the most common HLA susceptibility alleles. In this regard, other non-HLA genes are being considered to contribute to disease development [9, 10].

PBC displays immunologically characteristic features like biliary lymphocytic infiltrates, anti-mitochondrial antibodies (AMA) against the inner lipoyl domain of the E2 subunits of the pyruvate dehydrogenase complex, and elevated serum levels of IFN- $\gamma$  and TNF- $\alpha$ . The serologic hallmark of PBC is the presence of AMA [11, 12], which are found in 95% of patients with PBC [13] and have a specificity of 98% for the disease [12]. Auto-reactive CD4<sup>+</sup> and CD8<sup>+</sup> T cells are also found in high concentrations in the portal triads of patients with PBC, often surrounding and infiltrating necrotic bile ducts [14-16]. A

1  
2  
3  
4  
5 recent study suggested that a reduction in the number of CD4<sup>+</sup>CD25<sup>+</sup> regulatory T cells  
6  
7  
8 in livers affected with PBC contributed to disease progression [17]. Accumulating data  
9  
10  
11 such as these support a direct role of T lymphocytes in the pathogenesis of PBC.  
12  
13

14  
15 The cytotoxic T-lymphocyte Antigen 4 (CTLA4) is an inhibitory receptor  
16  
17  
18 expressed on the cell surface of activated memory T cells and CD4<sup>+</sup>CD25<sup>+</sup> regulatory T  
19  
20  
21 cells that acts largely as a negative regulator of T-cell responses. Since the potential  
22  
23  
24 inhibitory functions of CTLA4 [18] may also trigger a break-down of immunological  
25  
26  
27 self-tolerance, polymorphisms affecting these processes could have significant effects  
28  
29  
30 on susceptibility to autoimmunity.  
31  
32

33  
34 The *CTLA4* gene is a primary candidate for genetic susceptibility to  
35  
36  
37 autoimmune diseases, including type 1 diabetes, autoimmune hepatitis [19, 20], and  
38  
39  
40 autoimmune pancreatitis [21]. In particular, two single nucleotide polymorphisms (SNPs),  
41  
42  
43 rs231775 (49AG) and rs3087243 (CT60), have been widely studied in PBC [22-24].  
44  
45  
46 Although early studies found an association between SNP 49G coding and PBC [22-24],  
47  
48  
49 ensuing reports showed negative relationships with susceptibility [25-30] or a positive  
50  
51  
52 association with liver damage [31]. A recent investigation reported that rs231725 in the 3'  
53  
54  
55 flanking region of *CTLA4* is associated with AMA-positive PBC in Caucasians [27]. In  
56  
57  
58 addition to *CTLA4* polymorphisms, HLA class II, IL12A, IL12RB, and several other  
59  
60  
61  
62  
63  
64  
65

1  
2  
3  
4  
5 candidate SNPs were disclosed as predisposition genes for PBC by a high-density  
6  
7  
8 genome-wide association study [9]. Since these SNPs have not been extensively  
9  
10  
11 examined in a large Japanese population, the present study sought to evaluate the  
12  
13 involvement of *CTLA4* SNPs and haplotype SNPs in susceptibility to PBC and disease  
14  
15  
16 progression in Japanese patients.

## 24 **2. Patients and Methods**

### 25 *2.1. Subjects*

26  
27 We analyzed a total of 576 subjects (308 PBC patients and 268 healthy  
28  
29 controls) collected from different two regions of Japan (Table 1). Cohort 1 consisted of  
30  
31 198 patients clinically diagnosed with PBC (173 women, median age 58 years old) and  
32  
33 170 healthy subjects who were seen at Shinshu University Hospital, Matsumoto, Japan.  
34  
35 Cohort 2 consisted of 110 patients clinically diagnosed with PBC (92 women, median age  
36  
37 61 years old) and 98 healthy subjects from the National Hospital Organization Nagasaki  
38  
39 Medical Center, Omura, Japan. The racial backgrounds of all subjects were Japanese.  
40  
41  
42  
43  
44  
45  
46  
47  
48  
49  
50  
51  
52  
53 Control subjects were volunteers from hospital staff who had indicated the absence of  
54  
55  
56 any major illnesses in a standard questionnaire. The diagnosis of PBC was based on  
57  
58  
59 criteria from the American Association for the Study of Liver Diseases [32]. Serum AMA,  
60  
61  
62  
63  
64  
65

1  
2  
3  
4  
5 specific for the pyruvate dehydrogenase complex-E2 component, was measured by the  
6  
7  
8 enzyme-linked immunosorbent assay as reported previously [33]. An index of greater  
9  
10  
11 than seven was considered a positive result. All patients were negative for hepatitis B  
12  
13  
14 surface antigen, antibody to hepatitis C virus, and antibody to human immunodeficiency  
15  
16  
17 virus. To evaluate associations between SNPs and disease progression, patients were  
18  
19  
20 classified into two stages based on their most recent follow-up [34]: early stage patients  
21  
22 were histologically in Scheuer stage I or II [35, 36] or of unknown histological stage  
23  
24 were histologically in Scheuer stage I or II [35, 36] or of unknown histological stage  
25  
26  
27 without liver cirrhosis, and late stage patients were histologically in Scheuer stage III or  
28  
29 IV or clinically diagnosed with liver cirrhosis or hepatic failure. All participants provided  
30  
31 informed written consent for this study, which was been approved by the institutional  
32  
33  
34  
35  
36  
37 ethics committee.  
38  
39  
40  
41  
42

## 43 2.2. CTLA4 SNP Genotyping

44  
45  
46 Genomic DNA from patients and controls was isolated by phenolic extraction of  
47  
48  
49 sodium dodecyl sulfate-lyzed and proteinase K-treated cells, as described previously [37,  
50  
51  
52 38], and adjusted to 10-15 ng/ $\mu$ l.  
53  
54  
55

56 The five *CTLA4* gene SNPs examined in this study (rs733618, rs5742909,  
57  
58  
59 rs231775, rs3087243, and rs231725) were genotyped using the 5' nuclease (TaqMan)  
60  
61  
62  
63  
64  
65

1  
2  
3  
4  
5 assay using primer, probes, and reaction conditions as recommended by the  
6  
7  
8 manufacturer (Applied Biosystems, Tokyo, Japan). These SNPs were selected based on  
9  
10  
11 previous reports [21-23, 26, 27], and were all located in the *CTLA4* gene; SNPs  
12  
13  
14 rs733618 and rs5742909 were in the promoter region, SNP rs231775 in exon 1, and  
15  
16  
17 SNPs rs3087243 and rs231725 in the 3' untranslated region (UTR). Polymerase chain  
18  
19  
20 reaction was performed with a TaqMan Assay for Real-Time PCR (7500 Real Time PCR  
21  
22  
23 System; Applied Biosystems) following the manufacturer's instructions.  
24  
25  
26  
27  
28  
29

### 30 31 *2.3. Haplotype-Genotype Estimation*

32  
33 The R package "haploview" [39] was used to evaluate the haplotype structure  
34  
35  
36 of the five examined *CTLA4* SNPs. Pairwise linkage disequilibrium (LD) patterns and  
37  
38  
39 haplotype frequency analysis for all SNPs in patients and controls were assessed by the  
40  
41  
42 block definition by Gabriel *et al.* [40].  
43  
44  
45  
46  
47  
48

### 49 50 *2.4. Statistical Analysis*

51  
52 The Hardy-Weinberg Equilibrium (HWE) test was done for each SNP between  
53  
54  
55 control and patient groups. The significance of allele distribution between PBC patients  
56  
57  
58 and healthy controls was assessed using the  $\chi^2$  test with the use 2 x 2 or 2 x 3  
59  
60  
61  
62  
63  
64  
65

1  
2  
3  
4  
5 comparisons. Fisher's exact probability test was used for groups with fewer than 5  
6  
7  
8 samples. A  $P$  value of less than 0.05 was considered statistically significant.  $P$  values  
9  
10  
11 were corrected using Bonferroni's correction by multiplying by the number of different  
12  
13  
14 alleles observed in each locus ( $P_c$ ).  
15  
16  
17  
18  
19  
20

### 21 **3. Results**

22  
23  
24 In total, five SNPs located in the CTLA4 gene were genotyped in 198 patients  
25  
26  
27 with PBC and 170 healthy controls in cohort 1 and 110 patients with PBC and 98 healthy  
28  
29  
30 controls in cohort 2 (Table 2). Hardy-Weinberg equilibrium (HWE) was observed for all 5  
31  
32  
33 of the examined SNPs in both control groups, and the minor allele frequencies of all  
34  
35  
36 SNPs were greater than 5%. In cohort 1, one SNP (rs733618) differed significantly from  
37  
38  
39 HWE ( $P = 0.03$ ) (Table 2), and the frequency of the minor A allele at rs231775 was  
40  
41  
42 significantly decreased (33.9% vs. 41.5 %, odds ratio (OR) 0.72, 95% confidence interval  
43  
44 (95% CI) 0.53-0.99,  $P = 0.042$ ,  $P_c = 0.209$ ) in 171 AMA-positive PBC patients compared  
45  
46  
47 with controls. Positivity for the major G allele (A/G+G/G) at rs231775 was significantly  
48  
49  
50 higher in patients with AMA-positive PBC than in healthy subjects (88.3% vs. 79.1%, OR  
51  
52  
53 1.96, 95% CI 1.08-3.53,  $P = 0.026$ ,  $P_c = 0.128$ ). Additionally, the allele frequency (61.7%  
54  
55  
56 vs. 53.2%, OR 1.41, 95% CI 1.04-1.92,  $P = 0.025$ ,  $P_c = 0.127$ ) and allele carrier  
57  
58  
59  
60  
61  
62  
63  
64  
65

1  
2  
3  
4  
5 frequency (86.0% vs. 75.9%, OR 1.96, 95% CI 1.12-3.41,  $P = 0.018$ ,  $P_c = 0.089$ ) of the  
6  
7  
8 major A allele at rs231725 were significantly increased in AMA-positive PBC patients  
9  
10  
11 compared with healthy controls. However, these statistical significances disappeared  
12  
13  
14 after correction for multiple testing. No significant differences were observed among the  
15  
16  
17 5 SNPs in cohort 2. The allele frequency (60.3% vs. 53.4%, OR 1.33, 95% CI 1.04-1.69,  
18  
19  
20  $P = 0.022$ ) of the major A allele at rs231725 was significantly increased in combined  
21  
22  
23 analysis (cohorts 1 and 2) of 273 AMA-positive PBC patients compared with 268 healthy  
24  
25  
26 controls (Table 3), but statistical significance was lost after correction for multiple testing  
27  
28 ( $P_c = 0.110$ ) (Table 3).  
29  
30  
31

32  
33  
34       Pairwise LD mapping confirmed that all alleles were in strong LD with an index  
35  
36  
37 of  $>0.8$ . A strong LD was detected in the same block for PBC patients and controls. We  
38  
39  
40 next evaluated haplotype association among AMA-positive PBC patients and healthy  
41  
42  
43 subjects in a combined analysis. To estimate haplotype frequencies and analyze  
44  
45  
46 haplotype association with PBC, we selected tag SNPs using the Tagger algorithm from  
47  
48  
49 the Haploview program. Four tag SNPs (SNPs 2 to 5: rs5742909, rs231775, rs3087243,  
50  
51  
52 and rs231725) were selected to capture most of the allelic diversity in the two cohorts.  
53  
54  
55  
56 The four estimated haplotypes showed a frequency of  $>5\%$  in 11 haplotypes created by  
57  
58  
59 expectation-maximization algorithms (Table 4). Haplotype 1 (CGGA) was significantly  
60  
61  
62  
63  
64  
65

1  
2  
3  
4  
5 associated with AMA-positive PBC susceptibility (59.7% vs. 51.9%, OR 1.37, 95% CI  
6  
7  
8 1.08-1.75,  $P = 0.0095$ ). No other haplotypes were associated with either susceptibility or  
9  
10  
11 resistance to PBC.

12  
13  
14 Evaluation of the 5 CTLA4 SNPs between AMA-positive and AMA-negative  
15  
16  
17  
18 subgroups revealed neither significant allelic associations (Table 5) nor significant  
19  
20  
21 haplotype associations (Table 6), even when compared for early or late stages (Table 5  
22  
23  
24 and 6). Moreover, a comparison of 17 orthotopic liver transplantation (OLT) PBC cases  
25  
26  
27 and 291 non-OLT cases revealed no significant differences in allele frequencies (Table 5).  
28  
29  
30  
31 In haplotype analysis, no statistical associations were found with OLT (Table 6).

#### 32 33 34 35 36 37 **4. Discussion**

38  
39  
40 This study revealed that haplotype 1 (CGGA) was significantly associated with  
41  
42  
43 disease susceptibility in 273 AMA-positive PBC patients, as well as overall in all 308  
44  
45  
46 PBC patients ( $P = 0.012$ ) (data not shown). This finding is in agreement with the  
47  
48  
49 Caucasian study by Juran *et al.* [27], and thus constitutes a promising susceptibility gene  
50  
51  
52 candidate. However, since the precise function of *CTLA4* SNPs remains undefined, we  
53  
54  
55 cannot exclude the possibility that these SNPs may only be a linkage marker for a yet  
56  
57  
58 unidentified SNP within the *CTLA4* gene. Sequencing of the entire gene and assessing  
59  
60  
61  
62  
63  
64  
65

1  
2  
3  
4  
5 the functional role of these SNPs will be required.  
6  
7

8 SNP rs231775 associated with PBC is commonly referred to as 49AG in several  
9  
10 studies [23, 24, 27, 31, 41]. Our finding corroborated a previous report [31], in which  
11  
12 49AG was not associated with susceptibility to PBC but there was a discrepancy in  
13  
14 association with liver damage that might have arisen from the number of cases analyzed.  
15  
16  
17  
18  
19  
20

21 49AG also appears to affect cell surface expression of CTLA4 by CTLA4-driven  
22  
23 down-regulation in response to T-cell activation [42]. This coding polymorphism is  
24  
25 located in a signal peptide that is cleaved from the functional protein, and has been  
26  
27 shown to affect glycosylation of the autoimmune susceptibility G allele, resulting in  
28  
29 diminished processing efficiency and thus decreased trafficking to the cell surface [43]. It  
30  
31 will be necessary to confirm the functional difference between patients with these SNPs  
32  
33 and T-cell activation in a future study.  
34  
35  
36  
37  
38  
39  
40  
41  
42

43 The rs3087243 SNP, also referred to as CT60, is located in the 3' UTR of the  
44  
45 *CTLA4* gene and reported to influence the production of the soluble isoform of CTLA4  
46  
47 (sCTLA4). The sCTLA4 mRNA encoded by the +CT60G-allele is produced at a reduced  
48  
49 rate compared with that encoded by the A allele. As sCTLA4, which is secreted by  
50  
51 resting T cells, is a suppressor of T-cell activation, it is conceivable that carriers of the  
52  
53 +CT60G-allele allele may be more susceptible to autoimmune diseases.[44] Although  
54  
55  
56  
57  
58  
59  
60  
61  
62  
63  
64  
65

1  
2  
3  
4  
5 studies from Canada and Italy found an association between PBC and the CT60 SNP  
6  
7  
8 [29, 41], other studies have since failed to confirm this association [27, 28], including  
9  
10  
11 ours.

12  
13  
14  
15 In haplotype analysis, haplotype 1 contained all of the known SNP risk alleles  
16  
17  
18 that have been functionally determined in other disease studies. These include the C  
19  
20  
21 allele at -318, which has been found to affect the expression of CTLA4 mRNA cell  
22  
23  
24 surface expression [45], the minor G allele at 49AG, reported to reduce cell surface  
25  
26  
27 expression of CTLA4 [42], and the G allele of CT60, which affects the expression of the  
28  
29  
30 soluble form of the CTLA4 molecule, indicating the possibility that this haplotype might  
31  
32  
33 contribute to PBC susceptibility in the Japanese population.  
34  
35  
36

37  
38  
39  
40 Lastly, Juran *et al.* have suggested that CTLA4 plays a role in influencing AMA  
41  
42  
43 development as well as progression to OLT in PBC based on their haplotype analyses  
44  
45  
46 [27]. Our data revealed no statistical significance in regards to AMA development or  
47  
48  
49 disease progression to cirrhosis or OLT, possibly due to the number of patients showing  
50  
51  
52 AMA negativity and proceeding to OLT being too small to evaluate. Another  
53  
54  
55 consideration is that disease progression in Japanese patients might have a stronger  
56  
57  
58 association with positivity for anti-gp210 antibodies as a risk factor of progression to  
59  
60  
61 hepatic failure than CTLA4 polymorphisms [46]. Further longitudinal follow-up studies in  
62  
63  
64  
65

1  
2  
3  
4  
5 larger cohorts are required to resolve this critical question.  
6  
7

8           In conclusion, we found that *CTLA4* gene polymorphisms had a modest, but  
9  
10 significant, association with susceptibility to PBC in the Japanese population and may  
11  
12 share a common susceptibility haplotype with Caucasians. The connection between  
13  
14 genetic variants and the function of the *CTLA4* gene remains to be addressed in future  
15

<u>4</u>	<u>C</u>	<u>G</u>	<u>G</u>	<u>G</u>	<u>3.8</u>	<u>5.4</u>	<u>0.2153</u>	<u>0.70</u>	<u>0.39-1.23</u>

PBC, primary biliary cirrhosis; OR, odds ratio; 95% CI, 95% confidence interval; \*, Proportion of indicated haplotype (%)

Values for n indicate two times the number of individuals since each person carries two haplotypes.

P value was calculated by a  $\chi^2$ -test 2 x 2 contingency table (df =1).

Table 5. Allele frequencies of CTLA4 SNPs in AMA, histological or clinical disease progression, and OLT states

SNP No.	Allele	AMA <sup>+</sup> *		<i>P</i>	Early *		<i>P</i>	non-OLT *		<i>P</i>
		(n=273)	(n=35)		(n=223)	(n=85)		(n=291)	(n=17)	
<u>1</u>	<u>C</u>	<u>43.2</u>	<u>38.6</u>	<u>0.459</u>	<u>44.4</u>	<u>38.2</u>	<u>0.167</u>	<u>42.6</u>	<u>44.1</u>	<u>0.863</u>
	<u>T</u>	<u>56.8</u>	<u>61.4</u>		<u>55.6</u>	<u>61.8</u>		<u>57.4</u>	<u>55.9</u>	
<u>2</u>	<u>C</u>	<u>89.6</u>	<u>88.6</u>	<u>0.800</u>	<u>90.0</u>	<u>89.2</u>	<u>0.783</u>	<u>89.3</u>	<u>91.2</u>	<u>0.736</u>
	<u>T</u>	<u>10.4</u>	<u>11.4</u>		<u>10.0</u>	<u>10.8</u>		<u>10.7</u>	<u>8.8</u>	
<u>3</u>	<u>G</u>	<u>63.9</u>	<u>57.1</u>	<u>0.267</u>	<u>63.9</u>	<u>61.2</u>	<u>0.531</u>	<u>62.9</u>	<u>67.6</u>	<u>0.576</u>
	<u>A</u>	<u>36.1</u>	<u>42.9</u>		<u>36.1</u>	<u>38.8</u>		<u>37.1</u>	<u>32.4</u>	
<u>4</u>	<u>G</u>	<u>74.4</u>	<u>68.6</u>	<u>0.300</u>	<u>74.7</u>	<u>71.2</u>	<u>0.380</u>	<u>73.7</u>	<u>73.5</u>	<u>0.981</u>
	<u>A</u>	<u>25.6</u>	<u>31.4</u>		<u>25.3</u>	<u>28.8</u>		<u>26.3</u>	<u>26.5</u>	
<u>5</u>	<u>A</u>	<u>60.3</u>	<u>52.9</u>	<u>0.235</u>	<u>60.8</u>	<u>55.9</u>	<u>0.270</u>	<u>59.5</u>	<u>58.8</u>	<u>0.942</u>
	<u>G</u>	<u>39.7</u>	<u>47.1</u>		<u>39.2</u>	<u>44.1</u>		<u>40.5</u>	<u>41.2</u>	

PBC, primary biliary cirrhosis; AMA, anti-mitochondrial antibodies; OLT, orthotopic liver transplantation;

SNP, single nucleotide polymorphism; \*, frequency (%)

*P* value was calculated by a  $\chi^2$ -test 2 x 2 contingency table (df =1).

Table 6. Comparison of CTLA4 haplotype frequencies in AMA, histological or clinical disease progression, and OLT states

Haplotype	SNPs No.				AMA <sup>+</sup> *	AMA <sup>-</sup> *	<i>P</i>	Early *	Late *	<i>P</i>	non-OLT *	OLT *	<i>P</i>
	<u>2</u>	<u>3</u>	<u>4</u>	<u>5</u>	(n=546)	(n=70)		(n=446)	(n=170)		(n=582)	(n=34)	
<u>1</u>	<u>C</u>	<u>G</u>	<u>G</u>	<u>A</u>	<u>60.1</u>	<u>52.8</u>	<u>0.245</u>	<u>60.5</u>	<u>55.9</u>	<u>0.292</u>	<u>59.3</u>	<u>58.8</u>	<u>0.959</u>
<u>2</u>	<u>C</u>	<u>A</u>	<u>A</u>	<u>G</u>	<u>25.5</u>	<u>30.0</u>	<u>0.415</u>	<u>25.1</u>	<u>28.2</u>	<u>0.430</u>	<u>26.1</u>	<u>23.5</u>	<u>0.738</u>
<u>3</u>	<u>T</u>	<u>A</u>	<u>G</u>	<u>G</u>	<u>10.3</u>	<u>10.0</u>	<u>0.947</u>	<u>10.3</u>	<u>10.0</u>	<u>0.909</u>	<u>10.3</u>	<u>8.8</u>	<u>0.781</u>
<u>4</u>	<u>C</u>	<u>G</u>	<u>G</u>	<u>G</u>	<u>3.5</u>	<u>4.3</u>	<u>0.720</u>	<u>3.1</u>	<u>4.7</u>	<u>0.346</u>	<u>3.4</u>	<u>5.9</u>	<u>0.458</u>

PBC, primary biliary cirrhosis; AMA, anti-mitochondrial antibodies; OLT, orthotopic liver transplantation; SNP, single nucleotide polymorphism; \*, Proportion of indicated

haplotype (%)

Values for n indicate two times the number of individuals since each person carries two haplotypes. *P* value was calculated by a  $\chi^2$ -test 2 x 2 contingency table (df =1).
